Cancer patients are more prone to infections because of their immunosuppressive state resulting from their malignancy and anti-cancer treatments. Delaying cancer treatments should be balanced with SARS-Cov-2 exposure and the increased risk of severe infection in an immunocompromised group of patients.

A survey study involving health care representatives from the international oncology community from 18 countries presented by Jerusalem et al. At the European Society for Medical Oncology (ESMO) Congress 2020, highlighted the extent to which COVID-19 has challenged the organization and delivery of cancer care. Overall, 60.9% reported that clinical activity was reduced at the peak of the pandemic, while nearly two-thirds (64.2%) cited undertreatment as a major concern, and 37% expected to see significant reductions in a clinical trial data. Cancer treatments canceled or delayed were surgery (in 44.1% of centers), chemotherapy (25.7%), and radiotherapy (13.7%). Earlier cessation of palliative care was observed in 32.1% of centers. Thirty-four percent of respondents reported that surgery was the treatment modality that was most affected by the pandemic, followed by chemotherapy (22.0%), radiotherapy (13.7%), checkpoint inhibitor therapy (9.1%), monoclonal antibodies (9.0%), and oral targeted therapy (3.7%) Increased use of granulocyte colony-stimulating factor in 34.8% and a decreased corticosteroid use in 21.9% was observed. Telemedicine, or teleconsultations were reportedly performed for 94.5% of follow-up visits. Also, approximately 82% of participants projected that they would continue with the use of telemedicine more frequently in their practices after the pandemic [1].

INCIDENCE OF COVID 19 INFECTION IN CANCER PATIENTS

Though most data suggest a higher incidence of COVID-19 infection in cancer patients when compared to the general population, there are conflicting results. Chinese reports the incidence of COVID infection to be 1% in cancer patients; a higher ratio when compared with 0.29% of infection rate in the general population [2].

A study of 1069 cancer patients in Madrid, Spain the incidence of COVID-19 infection was found to be 4.2% much higher than 0.62% incidence of the city population but an Austrian study found a similar and even lower incidence of SARS-Cov-2 infection in cancer patients compared to the general population [3, 4].

CLINICAL OUTCOMES OF COVID-19 INFECTION IN CANCER PATIENTS

The clinical presentation and outcome of COVID-19 infection in cancer patients can be heterogeneous. Some meta-analysis suggests that severe and lethal COVID-19 infection rate is higher in cancer patients particularly with hematological malignancies, lung cancer, metastatic disease, and in older patients having comorbidities including obesity. [5].

A meta-analysis including 32 international studies from Europe, Asia and the United States for a total of 46499 patients including 1776 cancer patients showed that cause mortality rates were found to be higher in cancer patients (RR, 1.66; 95% CI, 1.33 to 2.07; $P < .0001$); However, in a prespecified subgroup analysis of patients > 65 years of age, all-cause mortality was comparable between those with versus without cancer (RR, 1.06; 95% CI, 0.79 to 1.41; $P = .71$); and the intensive care unit (ICU) admission was also more likely in patients with cancer (26 studies, 15,375 patients; RR 1.56, 95% CI 1.31-1.87). The authors concluded that cancer is associated with worse clinical outcomes among patients with COVID-19. However, elderly patients with cancer may not be at increased risk of death when infected with COVID-19 [6].

In Spain, a hospital-based study showed that the fatality rate was 9.8 % in Covid-19 infected patients however, the mortality rate in cancer patients was 42.2% ($p = 0.0001$) [7].

In a study conducted in New York City Hospital, a total of 218 COVID-19-positive patients from a malignant diagnosis were identified. A total of 61 (28%) patients with cancer died from COVID-19 with a case fatality rate (CFR) of 37% (20/54) for hematologic malignancies and 25% (41/164) for solid malignancies. Six of 11 (55%) patients with lung cancer died from COVID-19 disease. Increased mortality was significantly associated with older age, multiple comorbidities, need for ICU support, and elevated levels of D-dimer, lactate dehydrogenase, and lactate in multivariate analysis. Age-adjusted CFRs in patients with cancer compared with noncancer patients reported a significant increase in case of fatality for patients with cancer. The authors suggest the need for proactive strategies to reduce the likelihood of infection and improve early identification of Covid-19 infection in vulnerable cancer patient population. It remains uncertain if cancer patients other than those with hematologic malignancies or lung cancer are at increased risk of severe outcomes from COVID-19 when the analysis is controlled for age, the mortality/morbidity associated with their cancer, and other comorbidities [8].

Lung cancer is a leading cause of cancer related mortality but also case fatality rates from COVID-19 infection are high in patients with lung cancer. One of the challenging issues in delivering cancer care for patients with lung cancer is that discrimination of clinical symptoms and radiological findings from COVID-19 infection, lung cancer involvement, and progression or other infective conditions can sometimes be very difficult. This difficulty may render the clinicians from delivering the optimal treatment. The Thoracic Cancers International COVID-19 Collaboration (TERAVOLT) registry is a multi-centre observational study composed of a cross-sectional component and a longitudinal cohort component 200 patients with COVID-19 and thoracic cancers from eight countries were identified and included in the TERAVOLT registry. 152 (76%) patients were hospitalized and 66 (33%) died. 13 (10%) of 134 patients who met the criteria for ICU admission were admitted to ICU; the remaining 121 were hospitalized, but were not admitted to ICU Univariable analyses

revealed that being older than 65 years (OR 1.88, 95%CI 1.00–3.62), being a current or former smoker (4.24, 1.70–12.95), receiving treatment with chemotherapy alone (2.54, 1.09–6.11), and the presence of any comorbidities (2.65, 1.09–7.46) were associated with increased risk of death. However, in multivariable analysis, only smoking history (OR 3.18, 95% CI 1.11–9.06) was associated with an increased risk of death [9].

THE EFFECT OF CANCER TREATMENT ON COVID-19 INFECTION

The international COVID-19 and Cancer Consortium registry including 928 cancer patients from the United States, Canada, and Spain with confirmed SARS-CoV-2 infection over one month (The most prevalent malignancies were breast (21%) and prostate cancer (16%) percent); 43 percent had active cancer and 39 percent had received chemotherapy treatment within four weeks of virus diagnosis. The use of any form of anticancer therapy (cytotoxic or noncytotoxic) within four weeks of infection was *not* associated with higher 30-day mortality rates. In multivariate analysis, independent factors associated with greater 30-day mortality included older age, male sex, former smoker, two or more comorbidities, Eastern Cooperative Oncology Group (ECOG) performance status of 2 or worse and active cancer (versus those in remission; OR 5.2, 95% CI 2.77–9.77) [10].

Cancer, patients who are receiving systemic anticancer treatments, have been postulated to be at increased risk of mortality from COVID-19 infection. In the UK Coronavirus Cancer Monitoring Project (UKCCMP), a study including 800 cancer patients with COVID-19 infection, 52 percent of patients had a mild COVID-19 disease course while 28% of patients died. After adjusting for age, gender, and comorbidities, chemotherapy and other forms of cancer treatments such as immunotherapy, hormonal and targeted therapies and radiotherapy in the past 4 weeks had no significant effect on mortality from COVID-19 disease [11].

Immunotherapy in the form of Immune Check Point Inhibitors (ICI) is being used in cancer therapy especially in metastatic lung cancer patients in recent years. The answer to the question of whether programmed death 1 (PD-1) blockade therapy which has an immunostimulating effect can alleviate the severity of disease from COVID-19 in patients with cancer is not clear. A study in New York State Memorial Sloan Kettering Cancer Center; 423 cases of symptomatic COVID-19 were diagnosed (from a total of 2,035 patients with cancer tested). Hospitalization rate was, 40% in the patient group, and 20% developed a severe respiratory illness and 12% died within 30 days. Age older than 65 years and treatment with ICIs were predictors for hospitalization and severe disease, whereas receipt of chemotherapy and major surgery was not [12].

A retrospective study of a single-center 69 patients with lung cancer who were diagnosed with COVID-19 examined the severity of the infection based on no or prior receipt of PD-1 blockade. Overall, the severity of COVID-19 in patients with lung cancer was found to be high, including the need for hospitalization in more than half of patients and death in nearly a quarter. After adjustment for smoking status, PD-1 blockade exposure was not found to be associated with an increased risk of severity of COVID-19 [13].

TESTING FOR COVID 19 IN CANCER PATIENTS

Patients with cancer *with* symptoms concerning for COVID-19 (e. g., fever, cough, dyspnea, hypoxia), *or* those with exposure to someone with COVID-19, should be offered to test. Alternative causes for their symptoms (eg, influenza, bacterial pneumonia, cancer progression, treatment-related side effects) must also be considered. For patients with cancer *without* symptoms of COVID-19, guidance regarding SARS-CoV-2 testing is evolving, and the approach among is variable. Given the risk of transmission from asymptomatic carriers, some institutions are routinely testing all cancer patients before immunosuppressive therapies, as long as testing capacity is not limited. However, this is not a widespread practice and it is not supported by guidelines from the *American Cancer Society* and *ASCO*. On the other hand, this policy is supported by updated guidelines from the *Infectious Disease Society of America*, which now recommends SARS-CoV-2 RNA testing in asymptomatic individuals before immunosuppressive procedures, regardless of known exposure to COVID-19. According to these guidelines, immunosuppressive procedures are defined as cytotoxic chemotherapy, solid organ or stem cell transplantation, long-acting biologic therapy, cellular immunotherapy, or high-dose corticosteroids [14-15].

Unnecessary testing could lead to a delay in the administration of antineoplastic therapy and additionally could increase the risk of exposure to COVID-19. SARS-CoV-2 RNA can be detected for several weeks after initial infection but does not distinguish between active and resolved infection. In patients with mild to moderate illness, replicating the virus cannot be detected after the first testing for the asymptomatic patient without a history of COVID-19. The task force recommended that only patients with hematologic malignancies should be tested for COVID-19 RNA before the initiation of outpatient antineoplastic [16].

Resuming antineoplastic treatment therapy in a patient who previously tested positive for COVID-19 or who has had presumed recent COVID-19 infection. The task force recommended that in a previously symptomatic patient with COVID-19, resumption of antineoplastic therapy be considered when COVID-related fevers have resolved for at least 7 days without the use of fever-reducing medications, there has been a substantial improvement in respiratory symptoms, and at least 14 days have elapsed since the onset of symptoms and/or initial positive COVID-19 test, whichever came earlier. Repeat COVID-19 RNA testing is not recommended. In a previously asymptomatic patient with COVID-19, resumption of antineoplastic therapy can be considered when at least 14 days have elapsed since the initial positive COVID-19 test and no symptoms have developed during this time. [16].

The task force recognized that certain patients may require additional time to recover before resumption of antineoplastic treatment. These include patients who experienced more severe symptoms due to COVID-19 (i.e., required hospitalization and/or supplemental oxygen), older patients, and patients with certain malignancies, such as lung cancer, hematologic malignancies [16].

COVID-19 testing is not recommended for most asymptomatic cancer outpatients, and antineoplastic treatment can be resumed after the resolution of fever or the passage of time in patients who have tested positive, according to an expert task force. Clinicians must weigh the benefits of initiating or resuming antineoplastic therapy against the risk of worsening outcomes related to COVID-19 [16].

SARS-CoV-2 RNA testing of asymptomatic patients without a history of COVID-19 only for those with hematologic malignancies before the initiation of outpatient antineoplastic therapy. For patients with solid tumors, including lung cancer, routine pretreatment SARS-CoV-2 RNA testing was not recommended, according to the online report in the Journal of the National Cancer Institute [16].

Previously symptomatic patients with COVID-19 can resume antineoplastic therapy when COVID-19-related fevers have resolved for at least 7 days without use of fever-reducing medications, there has been a substantial improvement in respiratory symptoms, and at least 14 days have elapsed since the onset of symptoms and/or initial positive SARS-CoV-2 test, whichever came earlier [16].

In previously asymptomatic patients who tested positive for SARS-CoV-2, resumption of antineoplastic therapy can be considered when at least 14 days have elapsed since the initial positive test if no symptoms have emerged during this time. Patients who experienced more severe symptoms due to COVID-19, older patients, and patients with certain malignancies (lung cancer and hematologic malignancies, for example) might require additional time to recover before resumption of antineoplastic treatment [16].

Other institutions leave the decision to individual clinician's judgment as to the immunosuppressive potential of the specific regimen. At some institutions, testing of asymptomatic outpatients before initiating anticancer treatment is limited to those with hematologic malignancies especially for patients with a B-cell hematologic malignancy who are receiving anti-CD20 monoclonal antibodies, which are associated with B-cell depletion, and severe lymphopenia. At many institutions, testing is offered to lung cancer patients who present for surgery, bronchoscopy, or high-risk outpatient testing (eg, pulmonary function tests), as well as to those who are symptomatic or potentially exposed to a virus carrier, but not to others [16, 17, 18].

TREATMENT OF COVID-19 INFECTION IN CANCER PATIENTS

All patients should be informed regarding the symptoms of COVID-19, trained in proper handwashing and hygiene, and advised to wear facial masks in public and minimize exposure to large crowds [14].

COVID-19 disease management is the same in cancer patients as in the general population. Many mild cases (e.g., fever, cough, and/or myalgias without dyspnea or hypoxia) and asymptomatic infections can be managed conservatively at home if individuals can be adequately isolated. However, patients with more severe disease may warrant a higher level of care. Agents used specifically for COVID-19 are reserved for patients with severe disease [19].

One area of the potential impact of specific COVID-19 treatments is in cancer patients who have been receiving anti-CD20 therapies, which induce rapid and prolonged B cell depletion. In a case report of a patient with persistent viremia from SARS-CoV-2 who had received rituximab for lymphoma, convalescent plasma resulted in rapid recovery [20].

Another issue is drug interactions between COVID-19 therapies and anticancer agents. The French Society for Oncology Pharmacy has published detailed information about these

potential interactions that may be of value in decision-making around the choice of both anti-COVID and anticancer therapy [21].

ASCO recommends that until more definitive information emerges, decisions about interrupting anticancer treatment in patients with active COVID-19 should be based on a clinical benefit: risk assessment that considers the risk of interrupting cancer treatment versus the still poorly defined risk of adverse COVID-19 outcomes in patients receiving active cancer treatment [14].

Although data are very limited, one small study and at least two case reports have suggested that the use of Bruton tyrosine kinase (BTK) inhibitors for patients with a chronic hematologic malignancy may be associated with less severe infection [22, 23].

Glucocorticoids may be beneficial for patients who are hospitalized with severe SARS-CoV-2 infection. In other situations, for patients who are receiving glucocorticoids for management of their cancer or treatment-associated toxicities, the decision as to whether to continue or discontinue in a patient diagnosed with COVID-19 must be individualized, and depends in part on the dose and indication for the glucocorticoid. As an example, decision-making for high-dose glucocorticoids in a patient with brain metastases or epidural spinal cord compression, or a serious immunotherapy-related adverse event, is more difficult and must be addressed on a case-by-case basis [24].

Some oral none immunosuppressive therapies such as hormonal therapies, including androgen deprivation therapy or drugs targeting activating mutations (epidermal growth factor receptor inhibitors or BRAF/MEK inhibitors) may be continued on a case-by-case basis [14].

According to ASCO guidelines, cancer therapy can be reinitiated if at least 24 hours have passed since the resolution of fever without the use of antipyretics, and there is an improvement in symptoms (eg, cough, shortness of breath). For asymptomatic patients, waiting at least 20 days after the initial positive test is recommended. For most patients, obtaining at least one negative SARS-CoV-2 test before reinitiating anticancer therapy is preferred [14].

Cancer patients who have a persistently positive test, despite symptom resolution should avoid treatment in the same infusion room with other uninfected cancer patients receiving chemotherapy until they convert to a negative test. ASCO guidelines suggest that specific areas and dedicated staff be designated for treatment of COVID-19-positive patients. Physical distancing rules and contact limitations remain essential components of cancer treatments amid the pandemic to protect the patient, the health care workers, and other non-COVID-19 patients being treated in the same center [14].

Department of General Surgery, Istanbul, Turkey

ABSTRACT

With the rapid incline of Coronavirus Disease 2019 (COVID-19) cases, healthcare staff was urged to get organized for this new period. While preserving personal protective equipment, general ward beds, and intensive care unit beds physicians face difficulties. Getting infected for surgical teams mean additional workload for the remaining staff and in some cases, loss of the senior surgeon. Only emergent surgical cases are suggested to be performed to keep the healthcare staff ready and healthy for further months. Surgical staff should be minimized and personal protective equipment should be provided for hospital staff. Basic knowledge of COVID-19, action plans, algorithms for emergency and elective surgeries are necessary for surgical teams.

Keywords: surgery, COVID-19, personal protective equipment

INTRODUCTION

In Wuhan, China, pneumonia cases with unknown cause occurred in December 2019 [1]. Then it was discovered that this pneumonia is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease spread throughout the world and on March 11, 2020, World Health Organisation declared pandemic and the disease was started to be called as Coronavirus Disease 2019 (COVID-19) [2].

DIAGNOSIS

In patients with COVID-19 diagnosis; fever, dyspnea, fatigue, and muscle pain are the most common symptoms encountered [3]. Also nearly half of the infected patients remain asymptomatic. The diagnosis is confirmed by the real-time reverse transcription-polymerase chain reaction of viral nucleic acid [4]. In the laboratory evaluation; elevated D-Dimer, ferritin, alanine aminotransferase, aspartate aminotransferase, creatine kinase, lactate dehydrogenase, leukopenia, and lymphopenia are detected [5]. Radiologically, multiple ground-glass appearance and bilateral opacities, infiltrates are reported in chest X-rays. It should be kept in mind that patients with normal X-rays can also be diagnosed with COVID-19. In patients with suspected clinical, laboratory, and X-ray findings, chest computed tomography (CT) is the next step for diagnosis. Ground glass opacities and parenchymal consolidation are some characteristic findings in chest CT. These findings are usually seen bilaterally, in peripheral zones and lower lobes of lungs [3].

PRECAUTIONS IN THE COVID ERA

With the rapid incline of COVID-19 cases, healthcare staff was urged to get organized for this new period. To reduce the exposure and keep the healthcare staff safe, it is important to minimize the number of surgical teams and healthcare providers. In high-risk interventions producing aerosols, healthcare providers should use personal protective equipment (PPE) such as disposable head caps, gloves, long sleeve waterproof coats, long shoe covers, FFP2 (filtering facepiece) and FFP3 facial masks [6]. Disease Control Center suggested canceling all the elective procedures to keep healthcare providers safe. So, the healthcare staff have a reduced exposure risk and can provide longer healthcare service for emergency surgeries [7].

Also, face-to-face outpatient visits of non-emergent patients were postponed in many hospitals. In the pandemic, all of the hospitals in Turkey, reduced the staff in the operating theater, rounds, canceled clinical routine meetings and student lectures were held online.

WHICH CASES AND HOW SHOULD WE OPERATE?

With the high transmission rate of the disease, workload and stress are high among healthcare providers. Getting infected in surgical teams mean additional workload for the remaining staff and at some cases, loss of the senior surgeon [8]. Only emergent surgical cases such as patients with life-threatening situations, active symptoms, and malignancy diagnosis should be performed in order to keep the healthcare staff ready and healthy for further months. Surgical staff should be minimized and personal protective equipment should be provided for hospital staff [6]. Efficiency in resource usage and reduction of the contamination risk may be provided by prioritizing the emergency surgeries and postponing elective surgeries, nonurgent procedures, and outpatient visits. To provide healthcare for nonemergent patients who were diagnosed with a disease; followup and treatment of these patient groups may benefit from remote medical care. Face-to-face visits may be replaced by video conferences [9].

Turkish Surgical Society suggests that in emergency surgery, patients should be tested for COVID-19 and every patient should be treated as positive unless proven otherwise. Personal protective equipment should be used [8]. Also, if the abdominal computed tomography (CT) is performed, thorax CT should be added. In elective surgeries, risk evaluation for COVID-19 should be done and a consent form stating that surgery has a high risk for COVID-19 disease, should be taken from the patient [10]. In the safe surgery algorithm, only emergency upper gastrointestinal endoscopies should be done. The laparoscopic procedure should not be used rather open procedures should be preferred. However, during the COVID-19 period, there is not a consensus on whether to do laparoscopy or laparotomy in emergency surgeries. Morris et al. suggested that laparoscopy can be used safely since no studies show COVID-19 is transmitted through aerosolized laparoscopic gas [11]. Also, with the laparoscopic approach, a hospital stay will be shorter so that more bed capacity could be provided for infected patient care and there will be less infection risk for the operated patient.

In the operating theater, a minimum number of medical staff should be assigned and all of them should wear PPE [6]. Positive pressure ventilation is preferred in the operating theater. All patients should wear a face mask if they are not intubated during the procedure. If a patient is proven to be COVID-19, the surgical procedures should be postponed if possible [10]. If resource usage is not done in a planned fashion, it is possible that soon, there will be a shortage of healthy senior surgeons, experienced medical staff due to infection .

When dealing with COVID-19 surgical patients, it is important to have a preemptive plan to minimize the risk of contamination. There should be separate pathways for suspected patients for operating theater transit. So that medical staff shortage is prevented due to unexpected viral spread [12]. A dedicated operation room is needed for COVID-19 patients and this room should be the nearest to the theater block entrance. Transfer routes should be short and transfer through these paths should be as quick as possible with a trained medical staff who wear PPE [12]. In the operating theater for COVID-19 surgical patients, a minimal number of medical staff should work and minimal material and if possible disposable material should be used. The operating theaters usually have positive pressure air exchange [13]. Negative pressure operating rooms with a high air exchange of ≥ 25 cycles/hour is suggested to minimize the infection risk [14]. Surgical theater should be sanitized after each procedure [12].

Alcoholic solutions are suggested to be used for hand sanitation. Also, PPE should be worn during the whole procedure. Goggles is crucial for preventing conjunctiva from viral transmission [15]. There is no research on whether there is a viral load in tissue samples or body fluid of the infected patient. But still, precautions with PPE should be taken before entering the surgery. Disposable materials are preferred to be used but if reusable materials are utilized they should be sterilized carefully. Also, ventilators should be disinfected with chloroderivate solution in a concentration $\geq 0.1\%$ or 1000 parts per million [16].

Each hospital should have a detailed internal protocol for emergencies with COVID-19 patients so that a safe surgical procedure may be planned for all medical staff [12].

ONCOLOGICAL OPERATIONS DURING THE PANDEMIC

In this public health emergency period, other than emergency surgeries, how to handle oncological surgeries is crucial. Postponing elective surgeries in order to maintain capacity in

the healthcare system reduces the risk of additional exposure to infection [10]. There is an erratic dilemma in dealing with cancer patients. On one hand, there is a concern of tumor progression, a decline in survival, and increased risk of complications; on the other hand, there is an increased risk of cancer patients dying from COVID-19. A safe delay strategy is needed for this issue. Turage et al. analyzed 4 million cancer patients and found out that most cancer surgeries can safely be postponed for at least one month without having a drastic impact on tumor progression or survival rate [17].

American College of Surgeons (ACS) divided COVID-19 period into three phases: semi-urgent setting, a period where hospitals have enough intensive care units and COVID cases does not increase rapidly; an urgent setting where intensive care units and mechanical ventilators are limited, operating theater supplies are limited and there is a rapid incline of COVID patients; phase 3, where all intensive care units and mechanical ventilators are full [18].

In a semi-urgent setting, for breast malignancies and emergencies, ACS recommended operating on malignancy recurrence, triple-negative, and HER 2 positive patients. Breast abscess, hematoma drainage, ischemic mastectomy flap, and autologous tissue flap revision are suggested to be operated in an urgent setting in phase 3 [18].

For gastrointestinal tumors, early-stage rectal cancers for which adjuvant therapy is not recommended, rectal cancers after neoadjuvant chemoradiotherapy with no regression, nearly obstructing rectal cancer, cancers with the risk of local perforation are suggested to be operated in the semi-urgent setting. In an urgent setting, nearly obstructing colon cancer where the stent is not an option and cancers with local perforation, should be operated. In phase 3, only actively bleeding, perforated, and obstructed cancers are suggested for operation [18].

EMERGENCY SURGERY IN THE COVID-19 PERIOD

Although elective surgeries are postponed in the COVID-19 pandemic, emergency surgeries such as the acute abdomen, trauma surgery, and emergency endoscopies cannot be delayed [19]. To deliver surgical care safely and effectively is the main goal. Nepogodiev et al reviewed 13 articles and found out that reducing elective surgeries will reduce the risk of infection, provide more beds in general ward and intensive care units for COVID-19 patients and boost the number of doctors to take care of COVID-19 patients [20].

American College of Surgeons stated that mesenteric ischemia, perforated hollow organs, necrotizing fasciitis, incarcerated hernia, close loop obstruction and patients in septic or hemorrhagic shock should be operated without delay as emergency cases [18].

Uncomplicated appendicitis could be followed with oral antibiotherapy while appendicitis with abscess or perforation could undergo percutaneous drainage. However, if conservative management fails, surgery should be the only choice [18]. Necrotizing soft tissue infections or large soft tissue abscess and large perianal abscess should be treated in operating theater [18].

SURGICAL EDUCATION DURING THE PANDEMIC

In this unprecedented time of the COVID-19 pandemic, residents had flexible working hours and shift based schedules to take care of patients in order to minimize the exposure risk. Other than their own department, they had to work directly with COVID-19 patients so, they were more exposed to getting infected. Moreover, since they were only able to get involved in emergency surgeries, they had a quantitative loss of operation experience, clinical judgment, teaching, leadership skills, and basic patient-physician relationship [21]. In many countries, residents were engaged in virtual education and online theoretical sessions to recover the loss of education and training. Continuing surgical education is difficult in this era. However, with new ways of training the lost time will be recovered in a way [22].

TELEMEDICINE

During the pandemic, telemedicine becomes popular since many healthcare givers were able to contact their followup patients through this route. It reduced the visit time, cost, and increase patient satisfaction [23, 24]. Through video calls or teleconferences, suitable patients could be followed.

In surgeries with low postoperative complication risks or in patients who are already diagnosed with a disease and just need a close followup, telemedicine is an ideal approach to seek healthcare guidance [9]. In the COVID-19 period, teleconferences reduce face-to-face contact and also contamination risk. It also decreases the burden on outpatient clinics. However, before the application of telemedicine services, technological infrastructure and patient privacy issues should be considered with care [25].

Although many physicians are doubtful about any superiority of telemedicine to traditional outpatient clinic visits, some publications are supporting the applicability and cost-effectiveness of telemedicine [26, 9].

We believe that the first patient visit should be done face-to-face during the pandemic period since physical evaluation, the stress level of a patient is crucial for clinical decision making. After the first visit, according to the disease status and patient's compliance, telemedicine could be used.

CONCLUDING REMARKS

In the COVID-19 pandemic, it is important to keep healthcare providers safe by using personal protective equipment with great care and thus reducing the risk of contamination. All surgeons from different subspecialties should be trained to recognize COVID-19 patients. First, when physicians from other specialties such as internal medicine, infectious diseases, ear-nose-throat get infected or exhausted, they will be replaced with physicians from other specialties such as surgery. Second, in patients undergoing emergency surgery due to perforated gallbladder, bowel or mesenteric ischemia, it should be kept in mind that there can be concurrent COVID-19 [20]. Third, after an emergency or elective surgery, the patient could get infected with COVID-19 when observed in the general ward. [20].

The surgeons should think of their safety first to keep on working during this unprecedented period. Guidelines and recommendations for each hospital or country should be prepared. Strict rules on how to transport a COVID-19 patient for operation and protection measures that need to be taken before, during, and after surgery should be established. Guidelines for elective and emergency surgeries during the COVID-19 period will help the physicians to decide when and how to operate.

Chapter 468

CYTOKINE STORM AND OXIDATIVE STRESS IN SEVERE COVID-19

Yildiz Dincer*, PhD and Selin Yuksel, MSc

Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Medical Biochemistry, Istanbul, Turkey

ABSTRACT

Some patients infected with the SARS-CoV-2 virus show rapid progress to acute respiratory distress syndrome, multi-organ failure, and death. Acute respiratory distress syndrome is a large concern of death in COVID-19. Current therapeutic strategies focus on the virus itself and antiviral drugs are used to manage the disease. Unfortunately, the benefits of antiviral drugs are not satisfactory in every patient. It seems that the excessive inflammatory response rather than the virus titer is more relevant to the death. A brisk immune response generally destroys the virus but can cause significant local and long-term damage in tissues. In severe COVID-19, acute respiratory distress syndrome and multi-organ failure are associated with cytokine storm. Cytokine storm triggers the production of reactive oxygen species storm in immune system cells to destroy the virus. Although a certain amount of reactive oxygen species is helpful in the regulation of immune response and killing viruses, an excessive amount of reactive oxygen species damages the cellular lipids, proteins, and DNA. Extensive damage by reactive oxygen species results in apoptosis. Apoptotic death of endothelial and epithelial cells in the lungs plays important role in the development of acute respiratory distress syndrome in COVID-19 patients. Here, we will summarize the current molecular understanding of the vicious circle between the cytokine storm and oxidative stress that is an executive factor for cells.

Keywords: COVID-19, cytokine storm, reactive oxygen species, oxidative stress

INTRODUCTION

COVID-19 (coronavirus disease 2019) caused by the SARS-CoV-2 virus is spreading rapidly worldwide. No specific antiviral therapy and vaccine are available. Although many patients have mild or moderate symptoms, some patients show rapid progress to acute respiratory distress syndrome (ARDS), septic shock, multi-organ failure, and death [1]. In general, conditions such as advanced age, comorbidity, high body mass index are associated with severe disease. Besides, in COVID-19 survivors, life quality was observed to be low even 12 months after discharge from the hospital. Reduced lung function, reduced ability to exercise and mental health problems were seen in some survivors up to 6 months and beyond [2]. These long-term complications of COVID-19 in survivors indicate that not only acute executive conditions but also some long-term degenerative processes are triggered during the disease. Cytokine storm is a common feature in critically ill COVID-19 patients. Cytokine storm occurs due to uncontrolled activation of the immune system. It can lead to hyper inflammation, multi-organ failure, and can even die. Increased plasma levels of the cytokines including IL-2, IL-6, IL-7, IL-10, TNF- α , IFN- α , granulocyte-macrophage colony-stimulating factor (GM-CSF) were reported in severally ill COVID-19 patients [3].

CYTOKINE STORM IN COVID-19

Cytokine storm is a general term used to define abnormal cytokine release in response to infection and other stimuli. It occurs due to loss of regulatory control on proinflammatory cytokine production. The innate and adaptive immune responses activated by SARS-CoV-2 infection cause uncontrolled inflammatory responses leading to the cytokine storm [4]. Cytokines and chemokines are small peptides or glycoproteins that exert their actions by binding cell surface receptors. They act as signal molecule to activate immune system cells for chemotaxis and diapedesis and induce acute phase response. The overproduction of cytokines and chemokines increases the severity of the inflammation and a vicious cycle starts. The immune system is stimulated more than usual in patients with severe COVID-19. Especially if the patient had already got a chronic inflammation, the outcome gets worse. The cytokine storm can lead to excessive cellular damage that triggers apoptosis of epithelial and endothelial cells, vascular leakage, and finally results in acute respiratory distress syndrome (ARDS), multi-organ failure, and death [5]. The cytokine storm may be responsible for long-term complications of COVID-19 in survivors.

In viral infections, the body's first line of defense is the innate immune response. The SARS-CoV-2 virus induces a delayed elevation in the levels of proinflammatory cytokines and chemokines [6, 7]. In the early phase of SARS-CoV-2 infection, the release of cytokines and chemokines from respiratory epithelial cells, dendritic cells, and macrophages is delayed. Afterward, cells secrete low levels of antiviral factors, INF- α and INF- β , but high levels of proinflammatory cytokines such as interleukin (IL)-1 β , IL-6, and tumor necrosis factor (TNF) and chemokines such as C-C motif chemokine ligand (CCL)-2, CCL-3, and CCL-5 [8-10]. Publications indicate that interferon response is dysfunctional in critically ill patients during the pandemic COVID-19 [11]. IFN-1 α and IFN-1 β are the key molecules that trigger the innate immune response in the early stages of viral infections. IFN-1 α and IFN-1 β exert

antiviral activity by the induction of numerous interferon-stimulated genes that antagonize viral replication by various mechanisms. However, along with the activation of immune cells, SARS-CoV-2 expresses proteins that inhibit the synthesis of IFN-1 α and IFN-1 β thus weakens the immune responses and provides an optimal environment for rapid replication of the virus [12]. The low IFN-1 level at the onset of the disease delays the body's antiviral response. Afterward, the rapid increase of cytokines and chemokines attracts a large number of neutrophils, monocytes, and pathogenic inflammatory mononuclear macrophages to the infection site. Neutrophils migrate through the blood vessels and are recruited to the site of infection. Monocytes move into tissues and differentiate into macrophages. Excessive infiltration of these phagocytic cells into the lungs causes tissue damage, likely oxidative damage.

CYTOKINE STORM-INDUCED REACTIVE OXYGEN SPECIES PRODUCTION

When activated, all phagocytic cells bind and engulf pathogens to destroy. They can use oxygen-dependent and oxygen-independent mechanisms to kill pathogens. In oxygen-dependent systems, membrane-bound NADPH oxidase is activated, oxygen utilization increases (respiratory burst), and reactive oxygen species (ROS) are produced. ROS can cross the membranes of bacterial pathogens and destroy them by damaging their nucleic acids, proteins, and cell membranes. Superoxide anions produced by NADPH activity generate hydrogen peroxide (H_2O_2) via superoxide dismutase. The myeloperoxidase chlorinates H_2O_2 and produces hypochlorous acid (HClO) which is the strongest bactericidal agent. NADPH oxidase is a multi-protein complex that is made up of five components and a small GTPase protein, Rac2. Flavocytochrome b558 (cytb558) is found in the active site of the enzyme and transfers electrons from cytosolic NADPH to molecular oxygen. At resting state, cytb558 resides at the membranes of phagosomes, secretory vesicles, specific granules, and the plasma membrane. When neutrophils are activated, the regulatory cytosolic complex translocates to the membrane and interacts with cytb558 to activate NADPH oxidase. Activated GTP-bound Rac2 contributes to the assembly of the regulatory cytosolic complex [13]. Superoxide anions produced by the NADPH oxidase activity are the precursor in the generation of other ROS that all contribute to the destruction of the pathogens. In the presence of transition metal ions such as Fe^{2+} or Cu^{2+} superoxide anions can react with H_2O_2 to produce hydroxyl radical ($OH^\cdot$) that is the most active form of ROS.

Nitric oxide (NO) that is synthesized from arginine and NADPH by inducible nitric oxide synthase is the precursor of reactive nitrogen species (RNS). Superoxide anions can react with NO to produce peroxynitrite ($ONOO^-$), a strong oxidant. When the respiratory burst is triggered and superoxide anions are produced, if NO is present, peroxynitrite is generated as long as the respiratory burst lasts [14]. Superoxide anion is a short-lived ROS with limited diffusion within the cell, its cytotoxic effect occurs due to its derivatives including H_2O_2 , hydroxyl radical, and peroxynitrite. Both peroxynitrite and NO are toxic to mitochondria [15] leading to mitochondrial dysfunction which in turn increases superoxide anion production. Mitochondrial dysfunction is a general mechanism of ROS production detected in most viral infections because several viruses induce oxidative stress to facilitate their replication in the

host cell [16-18]. In viral infections, tissue damage occurs due to oxidative stress formed by cytokine storm and mitochondrial dysfunction. COVID-19 does share many similar symptoms with SARS and influenza. In an experimental study, viral replication increased rapidly and peaked on day 4, then reduced to baseline on day 8 in mice infected by the influenza virus. The lung damage index increased from day 2 and peaked from day 8 to day 10. Mice began to die from day 8 to day 14 [19]. ROS and NO in the infected mice started producing from day 5 and peaked on day 8 [20]. These results confirm the idea that cytokine storm triggers a ROS storm in COVID-19 and oxidative damage is responsible for worse outcomes in patients.

Pro-inflammatory cytokines including IL-6, TNF- α , IFN- α , IFN γ , and chemokines such as GM-CSF are up-regulated in COVID-19 patients [3]. IL-6, TNF α , GM-CSF, IFN γ can induce the production of ROS and RNS in neutrophils. IL-6 and IFN γ induce expression of NADPH oxidase. IFN γ triggers the production of superoxide anions by inducing NADPH oxidase 2 (NOX2) [21]. IL 6 induces expression of NOX2 in human aortic endothelial cells [22]. Nrf2 is a transcription factor that up-regulates the expressions of many antioxidant enzymes. It was reported that the overexpression of circulating IL-6 increases the ROS production and accumulation in the diaphragm muscle of adult NSE/IL-6 mice, by deregulating the nuclear factor erythroid 2-related factor 2-(Nrf2-) mediated antioxidant response [23]. Respiratory viral infections are associated with inhibition of NRF2-mediated pathways. These viruses have evolved to acquire the ability to suppress the Nrf2 pathway in their favor [24].

At the inflammation site, neutrophils express a large number of cell surface receptors including cytokine receptors such as tumor necrosis factor receptors (TNFRs), and toll-like receptors (TLRs). All receptors are G-protein-coupled. Ligand binding to these receptors can prime neutrophils for a more strong response if additional signals are available. Activation of these receptors induces tyrosine kinase and MAP Kinase activation. Both pathways stimulate the regulation of the NADPH oxidase components to cause activation of the enzyme. One group of the priming ligands are proinflammatory cytokines such as tumor necrosis factor TNF- α , GM-CSF, IL-1b, IL-8, and IL-18. IL-1b and IL-18 induce respiratory burst weakly but TNF- α and GM-CSF exert a strong priming effect [25]. TNF- α primes neutrophils for oxidative burst by inducing calcium flux and p38 MAPK-dependent mobilization of cytb₅₅₈ to the plasma membrane [26]. GM-CSF primes cells by inducing phosphorylation of certain residues on regulatory components which in turn promotes translocation and docking of the cytosolic complex to the membrane that is required for activation of NADPH oxidase [25, 27].

OXIDATIVE DAMAGE IN COVID-19

ROS are highly active chemical compounds that easily react with other molecules and damage them. The harmful effects of ROS occur in a few ways: (1) ROS can act as signaling messengers to stimulate inflammatory pathways, (2) ROS can impair cellular integrity and intracellular metabolism by oxidizing lipids, proteins, and nucleic acids (3) ROS can trigger apoptosis and lead to cell death, and organ failure, (4) ROS can consume antioxidant reserve and make macromolecules more vulnerable. The interaction between cytokines and ROS

constitutes a *vicious cycle* in which cytokines stimulate production ROS and then ROS form an oxidative signal that stimulates inflammatory signaling pathways. For instance, an increase in H_2O_2 level act as a signal to induce expression of the IL-2 and IL-4 and facilitate induction of the transcription factor NF- κ B which mediates induction of pro-inflammatory cytokines.

The harmful effects of ROS are counteracted by antioxidant enzymes and non-enzyme antioxidant molecules. Antioxidants inactivate ROS and prevent oxidative stress. Oxidative stress is a state in which ROS production overwhelms cellular antioxidant capacity. Cytokine storm leads to oxidative stress in COVID-19 patients by stimulating ROS production. While high ROS causes the rapid depletion of antioxidants, they also suppress the antioxidant defense mechanism by modulating Nrf-2 and/or NF- κ B pathways resulting in exacerbation of inflammation and oxidative stress [28]. According to preclinical studies, overproduction of ROS and disruption of the antioxidant system play a key role in the pathogenesis, progression, and severity of SARS-CoV infections [29-31].

ROS attack to membranes causes oxidation of membrane proteins and lipids which results in impaired membrane integrity and function. Oxidation of intra-cellular proteins leads to their denaturation and functional loss. Oxidized phospholipids were detected in human and animal lung cells infected with SARS viruses. Oxidized phospholipids can induce cytokine storm and lung injury in SARS-CoV infection [32]. On the other hand, the damaging effects of excessive ROS on the red blood cell membrane and heme group function play an important role in hypoxic respiratory failure observed in the most severe patients of COVID-19. Excess ROS can disrupt the lateral and transversal distribution and organization of red blood cell membrane lipids by oxidizing polyunsaturated fatty acids of phospholipids. This alteration affects the diffusion of oxygen and carbon dioxide and the deformability capacity of red blood cells in the capillary vessels which in turn favors thrombocytosis. Excess ROS can impair the function of hemoglobin to carry oxygen. Heme iron must be kept in the reduced state (Fe^{2+}) to bind oxygen. ROS excess can disrupt the Fe^{2+}/Fe^{3+} balance by oxidizing iron to a Fe^{3+} state. Fe^{3+} can not bind oxygen, resulting in less efficient oxygen transport despite a high oxygen supply [33].

Microvascular thrombosis is the most important aspect of severe COVID-19. COVID-19 infection appears to be hypercoagulability and vascular endothelial dysfunction [34, 35]. COVID-19 patients who present a hypercoagulability state characterized by longer prothrombin times, higher fibrinogen levels and inflammatory markers have statistically significantly worse outcomes [36]. Over-activation of neutrophils may be a potential explanation for the diffuse microvascular thrombosis and capillary leak syndrome observed in critical COVID-19 patients. Endothelial function plays a key role in the maintenance of vascular integrity and inhibition of excessive thrombosis. Oxidative stress that is induced by cytokine storm is one of the causes of endothelial dysfunction in COVID-19 [37, 38]. TNF- α can stimulate both mitochondrial and NADPH oxidase-mediated ROS and NO production in endothelial cells. TNF- α induced oxidative damage plays a critical role in endothelial dysfunction [39].

ROS interaction with nucleic acids causes oxidation of purine/pyrimidine bases and DNA strand breaks. All contribute the impaired cell metabolism and function. In the case of mild to moderate oxidative stress, DNA strand breaks, and oxidized bases are repaired by DNA repair systems. However massive oxidative DNA damage is fatal to the cells. When genomic damage exceeds the DNA repair capacity, apoptosis is triggered. Apoptosis is one form of programmed cell death. Apoptotic changes in endothelial cells were showed histologically in

COVID-19 [40]. Apoptosis of endothelial and epithelial cells damages the pulmonary microvascular and alveolar epithelial cell barriers and disrupts oxygenation by triggering coagulopathy in the alveolar vascular bed and vascular fluid leaking to the lung tissue. Therefore, apoptosis appears to be the most important pathogenic mechanism underlying ARDS. In cell culture experiments, a viral protease (SARS-CoV 3CL^{pro}) was found to trigger ROS production and apoptosis in the host cells [31, 41]. SARS-CoV 3CL^{pro} activates the NF- κ B-dependent reporter gene in HL-CZ cells. ROS-activated NF- κ B signaling induced by SARS-CoV 3CL^{pro} was suggested as a contributory factor in SARS-CoV pathophysiology [31]. All mitogen-activated protein kinases (MAPKs) are activated in the response of environmental stresses including oxidative stress and DNA damage derived from viral infections. A SARS-CoV's protease, the 3a protein, was found to be associated with the activation of apoptotic cell death through p38 MAPK activation [41]. In autopsy studies, hallmarks of apoptosis were observed in SARS-CoV-infected lung, spleen, and thyroid tissues [42].

In addition to ARDS, some patients develop various neurologic symptoms, ranging from hyposmia, headache, and dizziness to seizures and stroke. Severely affected patients are more prone to develop neurological damage than mild or moderate cases [43]. The neurological symptoms may be derived from the direct effects of the coronavirus on the nervous system and/or systemic effects of the disease. The local increased production of cytokines in the cerebral tissue can induce neuroinflammation, oxidative stress that are underlying pathogenic mechanisms of neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease. Particularly in elderly individuals, neurological damage that occurs due to COVID-19 may lead to serious neurodegenerative diseases in the post-COVID-19 term.

Figure 1. Cytokine storm-driven oxidative damage in severe COVID-19.

CONCLUSION

ARDS is a large concern of death in COVID-19. In severe COVID-19, the development of ARDS and multi-organ failure is associated with cytokine storm. When discussing the prevent ARDS and death in COVID-19, it is critical to understand that the closed-circuit between cytokine storm and oxidative stress is the executive factor for direct damage to cells and multiple organs. As a result of cytokine storm, the number of innate immune system cells increases in the inflammation zone and they produce an excessive amount of ROS and NRS to destroy the virus. In addition to killing viruses, ROS, and NRS damage cells by directly damaging or depleting cellular antioxidant reserves. The depletion of the antioxidant system exacerbates oxidative stress which in turn triggers apoptosis, causing cell death. Apoptotic death of endothelial and epithelial cells in the lungs is one of the most important causes of ARDS in critically ill COVID-19 patients. Elders and people suffering from diabetes, hypertension, and cardiovascular diseases have already a state of oxidative stress. SARS-CoV-2 infection will increase this stress. This may be the cause of the severity of COVID-19 in these categories of patients and elderly individuals. Astonishingly very few medical scientists mention the pivotal role of oxidative damage in patients with severe COVID-19. Current therapeutic approaches focus on the virus itself and try desperately to apply antiviral medicine. Unfortunately, the benefits of antiviral drugs are not satisfactory in every patient due to severe side effects. The suppression of the cytokine storm and oxidative stress may help to prevent tissue damage, save the patients' lives, and prevent complications after recovery. Drugs with antioxidant and anti-apoptotic properties may be helpful in the management of severe COVID-19 patients. In this context, anti-oxidative therapeutic strategy in COVID-19 was evaluated in the next chapter.

Chapter 469

ANTIOXIDANT AGENTS IN THE TREATMENT OF COVID-19

Mujgan Cengiz*, PhD

Department of Medical Biology, Cerrahpasa Medical Faculty,
Istanbul University Cerrahpasa, Istanbul, Turkey

ABSTRACT

SARS-CoV-2 (Severe Acute Respiratory Syndrome Coronavirus-2) belongs to the beta coronavirus family and shows an important global spread that is forcing the worldwide health care capacity, economic and social public life. It was referred that this deadly infection (COVID-19) has resulted in more than 1 million deaths and a lot of multiorgan failure around the world. The virus seriously affected people of old age, chronic cardiac problems, chronic respiratory syndromes, and hypertension. But in some cases, the disease may have a moderate or asymptomatic indication. Oxidative stress occurs because of an imbalance in the organism between the formation of the oxidizing system and antioxidant mechanisms. After the production of free radicals, antioxidant enzymes such as glutathione, melatonin, quercetin, curcumin, and vitamins, play an important role in neutralizing the effects of free radicals. The imbalance of oxidative stress and accumulating free radicals may get involved in the formation of cancers, degenerative diseases, hypertension, diabetes mellitus, heart and vessel diseases, and virus infections, especially RNA viruses like HIV 1, SARS, MERS, and coronaviruses.

A common approach in COVID-19 infection is the disruption of the antioxidant balance so free radicals can be exposed and accumulate in the organism. The depletion of the glutathione content, which is the most common antioxidant molecule of the tissues, causes the organism to increase the inflammation.

In this article, we will discuss the role of free radical mechanisms in the formation of infection by COVID-19 and the treatment of the disease by different antioxidants such as GSH, melatonin, vitamins (C, D, E, A), and food additives.

Keywords: COVID-19, antioxidants, glutathione, vitamin, flavonoid

INTRODUCTION

Free radicals are chemical products that carry an unshared electron in its outer orbit. They are formed by the release of an electron from a non-radical atom or molecule, or by the addition of an electron to an atom or molecule. Free radicals are produced in animals and plants during aerobic metabolism and reduce the effects of the antioxidant activity or amount of compounds, as to behave as antioxidants (albumin, melatonin, urea, glutathione, vitamin D), exogenous antioxidants (vitamin E, vitamin C, vitamin A, polyphenols, curcumin), and enzymes (superoxide dismutase (SOD), glutathione peroxidase (GPx), glutathione S transferase (GST), catalase (CAT)). Dietary antioxidants are beneficial in protecting against free radicals. Decreasing amounts of them cause the death of cells by lipid peroxidation, protein and DNA damage. They play an important role in preventing many diseases in humans, e.g., infection diseases, cardiovascular diseases, and cancer. Antioxidant enzymes and other non-enzyme antioxidants exhibit synergistic effects in scavenging free radicals.

Large different kinds of chemical carcinogens, viruses cause the formation of DNA and protein hazards and require activation by enzyme systems like cytochrome P450 [1]. In opposite to this situation, phase 2 xenobiotic-metabolizing enzymes and compounds such as Glutathione related enzymes (Glutathione peroxidase, glutathione s transferase, glutathione reductase), NAT (N-Acetyl Transferase), epoxides hydroxylase, sulfotransferase, GSH and NO takes place in the detoxification of chemicals, viruses, and consequently, known to be protective [2].

For a long time, the association of the environmental risk factors such as viruses was interesting for researchers. They increase oxidative stress that is triggered by various viral infections such as reactive oxygen species (ROS) production that disrupts the cell membrane integrity, and mitochondrial dysfunction [3]. Most of these viruses are RNA viruses which are, herpes viruses, respiratory viruses, HIV 1, viral hepatitis, and coronaviruses. Coronaviruses are single-stranded and encapsulated viruses which shown in 3 types: the classic coronaviruses, responsible for mild respiratory infections in general, the SARS-CoV and second one MERS-CoV (Middle Eastern respiratory syndrome) seen in epidemics of severe respiratory infections, and the third one; new coronavirus (caused by SARS-CoV-2) spread in December 2019 responsible for an infectious disease called COVID-19 which is currently accomplishing a worldwide pandemic [4].

Generally, viral infections produce an augmentation in the production of free radicals and a reduction of antioxidant capacity in the organisms in which they live [5]. This was previously shown in a study of HIV infection [6]. Oxidative stress caused by RNA virus infections can take part in the formation of several aspects of viral disease pathogenesis which are apoptosis, disruption of the immune system, viral replication, increased inflammatory response. SARS-CoV-2, MERS-CoV, and COVID-19 infections increase oxidative stress and ROS increases in the cell and disrupt the mitochondria after the cells get infected with these viruses. The release of acute-response cytokines (TNF and IL-1 β), chemotactic cytokines (IL 1, IL 6, IL-8, and MCP-1) increases (Figure 1).

Increasing these cytokines causes a shock by hyper inflammation and generates a lot of ferritin by the reaction of Fe²⁺ by hydrogen peroxide and increases OH⁻ radicals, ROS and Fe³⁺. Because of this dysfunction, interleukins increase in the organism, and the cytokine storm begins [7]. In studies, the oxidative storm also investigates that lipid peroxidation and

protein oxidation may disrupt the alveolar membranes and cause serious respiratory problems [8]. Elderly people and patients with hypertension, diabetes, obesity, and cardiovascular diseases are affected by the virus more than healthy and young people do because of the existing accumulation of oxidative stress [9].

Figure 1. Mechanism of SARS-CoV-2 after entering to the organism. Pattern recognition receptors (PRR), pathogen-associated molecular patterns (PAMPs). Interleukin (IL). TNF(tumor necrosis factor).

In the people infected by COVID-19, the antioxidant therapy aims to reduce the number of oxygen radicals by reducing oxidative stress with substances such as Glutathione and its precursors like N acetylcysteine, melatonin, vitamin C, vitamin D, some substances like curcumin and quercetin.

EXAMPLES OF MEDICALLY USED ANTIOXIDANTS

Glutathione

GSH (glutathione) consists of a tripeptide (cysteine, glycine, and glutamate) and is the most abundant antioxidant in the whole body and has a master role in most of the organisms to reduce the oxidative stress caused by an increase of ROS (reactive oxygen species) [10].

As a substrate of the GSH redox cycle, it is useful in scavenging singlet oxygen with hydroxyl radicals. In addition to directly scavenging free radicals; it also acts enzymatically with GPx. GSH plays a vital role in keeping enzymes and other cellular components in the cells in a reduced state. GSH is mostly synthesized in the liver and about 40% of it is excreted in bile. It is spread % 85 in the cytosol, the lesser amount at the subcellular parts of the cell which are; mitochondria, endoplasmic reticulum, and nucleus [11]. Its amount is measured 0.1-10 mM in living cells [12]. It reduces the amounts of ROS by using the reduced GSH to form oxidized GSSG (glutathione disulfide). Another important GSH function is to support the maintenance of the intracellular redox balance and thiol levels in the cell [13, 14] In the case of inflammation diseases, intrinsic oxidative stress has been found as depletion of total free thiol levels (free sulfhydryl, free thiols, and glutathione) [14]. It is found in most cells especially in upper and lower respiratory tract epithelial cells fluids and it protects the nose throat and lungs from pro-inflammatory processes. Glutathione has increased the immune response at herpes and influenza by blocking their replication [14].

The glutathione synthesis may increase by the GCS (gamma-glutamyl synthetase), this is a rate-limiting step for the synthesis and causes a rapid increase at the amount of the GSH. The other synthesis way is the induction of GCS by Nrf2 (The nuclear factor erythroid 2-related factor 2). Nrf2 is a transcription factor that increases the expression of a group of antioxidant, anti-inflammatory, neuroprotective protein [15].

In a study, N acetylcysteine, a GSH precursor, was given to two COVID-19 infected patients and it is found that this treatment inhibited the cytokine storm by blocking NF Kappa B (Figure 1) [16]. They applied glutathione to the patients infected by COVID-19, they showed the relieving of the respiratory symptoms. The increasing amount of GSH induce the Nrf2 and this inhibits the excess cytokine production that causes cytokine storm. In this study, the authors also used potent Nrf2 activators such as curcumin and sulforaphane.

In another study from Russia, it is postulated that increased age may reduce the synthesis of glutathione and the antioxidant protection may disrupt because of this reason [17].

According to various studies, this hypothesis recommends that the SARS-CoV-2 virus shows a major risk for people with endogenous glutathione deficiency, anyhow which of the factors old age, chronic disease, comorbidity, smoking, cardiovascular diseases, and obesity were responsible for this defect [18, 19, 20]. The hypothesis shows a new explanation into the etiology and mechanisms responsible for the serious appearance of COVID-19 infection and proves the right promising statutory for powerful treatment and controlling of the illness through glutathione rescuing with N-acetylcysteine and reduced glutathione.

Onward the antiviral influence of glutathione is non-standard, there is cause to count on that glutathione is also effective against COVID-19. Therefore, increasing glutathione levels in COVID-19 patients would be an encouraging perspective for saving the health of the new coronavirus for SARS-CoV-2 infection also.

Melatonin

Melatonin (*N*-acetyl-5-Methoxytryptamine) is a natural antioxidant molecule synthesized from tryptophan in the pineal gland and all organs of the body because its synthesis occurs in the mitochondria [21]. It neutralizes antioxidant molecules ten times more than vitamins C

and E that binds only one. The antioxidant effects of melatonin are connected to the increased activity of superoxide dismutase, glutathione S transferase, reductase, peroxidase, and catalase [22, 23].

COVID-19 caused long-term stress in people resulting in anxiety and sleep defects.

Sleep defects may have negative effects on the immune system [24]. Prolonged anxiety causes a decrease in the amount of the immune cell and increases immunosuppressive mechanisms (increases T Cells). Inflammation and oxidative stress are implicated together in COVID-19 pathogenesis [25]. Oxidative stress-sensitive genes were stimulated in the peripheral blood mononuclear cells of SARS-CoV-2 infected patients [26]. Melatonin is found as a free radical scavenger and antioxidant at researches [27]. The metabolites of melatonin are cyclic-3-hydroxymelatonin (c3OHM), N1-acetyl- N2-formyl-5-methoxykynuramine (AFMK), and N1-acetyl-5-methoxykynuraminem (AMK) are produced by true scavenging free radicals. These metabolites have also been indicated to have protective properties of the melatonin [28]. Besides this, melatonin and its metabolites act as anti-excitatory agents that reduce prooxidant enzyme activity, inducing glutathione synthesis, and it elevates antioxidant enzyme synthesis. Furthermore, melatonin plays a significant action in ameliorating mitochondrial function with mention to the promotion of mitochondrial complex I and complex IV activities and inhibits of electron loss [29].

According to the studies, melatonin can not destroy the virus directly but it has an indirect antioxidant and immune system enhancer [28, 30]. In a study performed by respiratory virus models, melatonin caused a serious decrease in acute lung oxidative injury, depressed pro-inflammatory cytokine release, and inflammation in the cell [31].

Nevertheless for using this supplement the safety and side effects should be investigated. Metionin's characteristics scavenging free radicals show antioxidant property and increase in the immune system and may cause its potential decrease of COVID-19 infection.

A significant number of the long and short term of clinical studies suggest the safe use of melatonin up to 100 fold higher its physiologic concentration [32, 33]. Further, the brain is the organ where the number of drugs at the lowest level after melatonin administration, which could excuse the use of high doses for the potential treatment of SARS-CoV-2 [32].

Vitamin C

Ascorbic acid (vitamin C) is a very vital vitamin for the overall health and development of humans and other animals because it protects these organisms from serious diseases. It exists especially in vegetables and fruits [34]. It's synthesized from glucose in the liver of different mammalian species, permitting the preservation of physiological levels at the organisms. However in some species, including humans, it does not have the functional enzyme for the last step of the synthesis that's why they have to use exogenous sources of ascorbic acid [35]. It has very different effects on the rearranging the immune system of the organisms. The most important function and need for using of vitamin C is its antioxidant property to decrease the reactive oxygen radicals, which responsible for free radical hazards, biomolecular, cellular, and tissue damage related diseases, as well as cancer, atherosclerosis, and virus infections [36, 37]. Vitamin C also has been shown to increase the migration of neutrophils to the infection region, stimulating phagocytosis, and ROS generation [38].

Because of the required high need, it's recommended that the human daily intake of vitamin C (60 mg) is the highest of all vitamins [39].

The antiviral properties of ascorbic acid were known and it was searched around for a long time before [40, 41]. It has been applied to patients who were infected by influenza and herpes and found healing for these patients [42]. COVID-19 pneumonia is a serious disease with the risk of death with chronic organ disorders. This helps to provoke severe lung injury which causes Acute Respiratory Distress Syndrome (ARDS), causes a deadly injury in the lungs. This process inhibits adequate oxygen to enter into the lungs and at last cause death. Coronaviruses increase oxidative stress that promotes cellular damage and the results in organ failure. It is thought that pulmonary failure (ARDS) is the main reason for COVID-19's action on humans. This causes to increase in oxidative stress markedly because of the production of free radicals and cytokines. This action causes important cellular injury, organ damage, and death. The application of anti-oxidizing agents forward with known antioxidant property counts on to have a serious role in stopping these medical symptoms. Although evidence for the consumption of vitamin C for healing COVID-19 infections is not strong enough, there were studies from investigations of vitamin C in other respiratory diseases to begin conducting [43]. In a meta-analysis published by Ran, it is concluded that daily supplementation in vitamin C with more than daily doses decreases the time of period having a catching cold [44]. In acute lung injury and ARDS as seen in COVID-19 infections, overage neutrophil aggregation in the inflammatory region causes lung tissue damage via the release of necrotic cell ingredient [44], and vitamin C is declared to prohibit this action [45]. The antiviral characteristics of vitamin C may support depress symptoms and death seen in COVID-19 cytokine storm and could be a promising candidate for the treatment [46].

Vitamin D

Vitamin D is a steroid hormone that classically regulates bone calcium and phosphate metabolism, modulates the immune system, and its insufficiency is related to increased autoimmunity as well as enhances sensitivity to infection [47]. Its decreased amount is an important health problem seen all age range worldwide. In the last years, the relationships between low levels of vitamin D and various diseases has been shown by several studies, it increases innate and adaptive immunity, secretes antiviral peptides and augments mucosal resistance, improves membrane permeability [48, 49]. The studies have shown that the vitamin D₃ synthesized in the skin by the UVB radiation is converted to the 25(OH)D in the liver and it has changed to its active form 1,25-dihydroxy vitamin D in the kidney and other organs [49]. In human normal serum 25(OH)D levels in between 40-60 ng/mL (100-150 nmol/L) [50].

These vitamin D amounts are stable with the published studies for decreasing the risk of various types of immune system diseases, cancers, cardiovascular diseases [51, 52, 53]. Several reviewers consider that the relationship between low level of serum 25(OH)D and the effectiveness and severity of respiratory tract infection in children and adults [54, 55, 56]. At a prospective study in healthy individuals, it is found that the acute respiratory tract infection reduced at the patients which have high levels of vitamin 25 (OH) D (38 ng/mL) in their serum [56]. In another study carried out in New Zealand children aged less than 2 years,

showed the severity and hospitalization of acute respiratory infection percentage higher at the vitamin D deficiency [55]. This may explain the preventive effects of sufficient vitamin D status against respiratory viral infection. 1,25(OH)₂D shows anti-viral activities by increasing innate immunity by enhancing the antimicrobial peptides and regulates inflammatory reply to viral infection by adjusting of toll-like receptor generation and NK cells production, inhibiting excess expression of proinflammatory cytokines [54]. Besides the immune modulatory and anti-viral influences, 1,25(OH)₂D may act as to the disposition of the renin-angiotensin pathway and decreases the angiotensin-converting enzyme-2 expression, which may act as the subjects cell receptor which regulates infection of SARS-CoV-2 [56]. In a study done at African American and obese individuals, it is observed high morbidity, mortality and increased hospitalization at these subjects may be depends on their vitamin D deficiency [58].

Flavonoids

Flavonoids have a lot of secondary metabolites, that are found in vegetables, seeds, fruit, and beverages, like red wine and green tea [59]. There are very different kinds of structurally identified flavonoid molecules such as hesperidin and quercetin.

These chemicals are synthesized in plants to protect them from stressful mediums and play an important role in defending the plant cells from pathogens and insects [59].

The prophylactic characteristics of flavonoids implicate antibacterial, antioxidant, anti-inflammatory, and antiviral functions. Flavonoids work to defend the organisms from a group of DNA and RNA viruses [60].

After spreading the COVID-19 pandemic worldwide, the interest of researchers to the potential therapeutics other than antiviral drugs, the utilization of flavonoids against coronavirus infection concentrated on the SARS-CoV-2 virus [60, 61].

Hesperidin is a common flavon glucoside which used as an herbal medicine continually. It is mainly found in citrus fruit such as lemon, orange, and grapefruit [62]. It has various activities against the viruses. It's the antiviral and anti-inflammatory activity has been attributed to it an antioxidant property and reduce the pro-inflammatory cytokine production. In a study after SARS-CoV 2 pandemic, it has been shown that COVID-19 uses the ACE-2 receptor for entering the organism the serine protease TMPRSS2 for priming of S-protein. Recently in a work Camostat mesylate used which a serine protease inhibitor drug blocked virus entry and was used as a COVID-19 treatment has been shown in research [63].

Another flavonoid compound quercetin was studied for their chemical activity in searching capillary wall resistance [64]. The *in vitro* and *in vivo* investigation shows that Quercetin affects the organism as a free radical scavenger, which gives two electrons by o-quinone/quinine methide [65], studies also in agreement that quercetin as a potent antioxidant [65, 66].

An important flavonoid naringenin has the chemical name of 4' 5 7-trihydroxyflavone, is accepted as a very important flavonoid, mostly a flavanone, because of its potential biological activities such as antioxidant, anti-inflammatory, and antiviral food additive. In a recent meta-analysis, it was indicated that naringenin may show curative effects against COVID-19 via

inhibition of COVID-19 main protease, 3-chymotrypsin-like protease (3CLpro), and decreasing of angiotensin-converting enzyme receptors activity [67].

CONCLUSION

In a conclusion During the COVID-19 pandemics, as in all other health conditions, or saving health, it is recommended sustainable nutrition which affluence in antioxidant food. Glutathione, melatonin, Vitamin C, and D play an important role in regulating the immune system. But it can not evaluate these supplemental amounts of the vitamins that might give an efficacy. Some reports show the benefit of intra-venous utilization of vitamin C at the high dose in hospitalized COVID-19 patients [43, 68]. Vitamin D insufficiency has been associated with an increased probability of respiratory tract infection, therefore it is sensible, even in enough of specific data, to give vitamin D to healthy individuals and COVID-19 patients [48, 55, 57]. Flavinoids also found increased cell defense mechanisms against the COVID-19 virus [61, 62]. The diet is also important nutritional supplements, researches recommend advice for preventing and healing COVID-19, but the important size of clinical research data is required to support that suggestion.

ABSTRACT

The ongoing coronavirus disease (COVID)-19 pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has affected people worldwide both sociologically and economically. This crisis might be controlled by a safe, tolerable, and immunogenic vaccine. Multiple vaccines are in development, and some of them are even in phase III trials but, no approved efficacious vaccine is currently available. Vaccines protect from infection, reduce symptom development, lower mortality rates, and reduce the extent of virus circulation. Therefore, hopefully in the near future, when the vaccine is roll-out, we can overcome this pandemic by informing the people correctly on vaccine safety and importance for public health and by vaccinating susceptible people in the most effective policies.

Keywords: COVID-19, SARS-CoV-2, vaccine, pandemic

INTRODUCTION

The first SARS-CoV-2 case identified in December 2019 within a month, the genetic sequence of the virus became available (MN908947.3). On 11 March 2020, the World Health Organization (WHO) declared the SARS-CoV-2 outbreak as a pandemic. Since then, the virus has infected millions of people globally [1]. Current public health interventions aimed at blocking the spread of SARS-CoV-2 have been limited to nonpharmaceutical interventions (NPIs), including travel-associated quarantines, contact tracing, mask usage, and implementation of social distancing regulations. These measures have had various degrees of

* Corresponding Author's Email: gokhanaygun67@yahoo.com.

success worldwide. While critical to slowing viral spread, some of these NPIs have resulted in widespread job loss and economic hardship. Considering the substantial political and economic costs associated with NPIs, long-term and effective solutions are needed [2, 3].

In this context, the vaccine remains the most promising solution. Thanks to devoted research efforts worldwide, vaccine development is well underway, with more than 100 vaccine candidates in clinical trials, including candidates in phase III trials. Clinical trials for SARS-CoV-2 vaccines evaluate both the safety and efficacy of vaccine candidates. Ethically, a vaccine cannot be licensed if it does not provide a direct protective benefit to the vaccine. Direct protective benefits of vaccines include protection from infection, reduced symptom development, and lower mortality rates [4].

For vaccine-preventable diseases, not all susceptible individuals can be immunized for various reasons, such as they are too young or too old to be vaccinated, they have co-morbidities and weakened immune systems or they reject the vaccination for cultural, traditional, or religious reasons. The question then is what is the minimum proportion of those we can vaccinate that we need to vaccinate so that those that we cannot vaccinate can be protected from developing severe disease or dying of the disease. The notion of herd immunity in the transmission dynamics is associated with the indirect protection against acquisition of a communicable disease, members of the community receive when a large percentage of the population has become immune to the infectious disease due to natural recovery from prior infection or vaccination. The consequence of herd immunity is that individuals who are not immune (e.g., those who cannot be vaccinated or those who have not been infected yet) receive some protection against the acquisition of the disease. The safest and fastest way to achieve herd immunity is obviously vaccination [5]. This indirect effect decreases the infection risk of both vaccinated and unvaccinated susceptible individuals by reducing the extent of virus circulation in a community. Virus circulation can decrease because vaccinated individuals are less susceptible to infection, or because vaccinated individuals have shorter durations of infection or lower viral loads that reduce their infectiousness. Vaccination campaigns can significantly reduce the number of infections and deaths in subpopulations that remain unvaccinated, even when the vaccination percentage is quite low [6]. The vast majority of the global population remains susceptible to the virus and we are likely well below the herd immunity threshold, despite the staggering rates of infection that some regions have already experienced. Therefore the indirect effects of vaccine candidates are critically important to consider when evaluating SARS-CoV-2 vaccine candidates and formulating strategies for their roll-out. Clinical trials to test vaccine effectiveness do not evaluate population-level effects. Quantifying both the direct and indirect effects of vaccines on population-level outcomes, such as disease incidence and mortality, requires evaluating data after a vaccine has been in use for some time. Therefore, mathematical models are needed to assess the potential indirect effects in advance.

With the hope of producing a vaccine in the near future comes the difficult task of deciding who to vaccinate first as vaccine shortages are inevitable. According to our knowledge on COVID-19 so far, children are less susceptible to infection than middle-aged adults (20 to 65 years old), while older adults (older than 65) were relatively more susceptible. Studies showed that a vaccine with an effectiveness $\geq 50\%$ would be enough to substantially mitigate the ongoing pandemic provided that a high percentage of the population is optimally vaccinated [7]. When minimizing deaths, for low vaccine effectiveness (VE), it is optimal to allocate vaccine to high-risk (older) age-groups first. In contrast, for higher vaccine

effectiveness, there is a switch to allocate vaccine to high-transmission (younger) age-groups first for high vaccination coverage [8]. Any vaccine with medium to high effectiveness ($VE \geq 50\%$) would be able to considerably slow the epidemic while keeping the burden on healthcare systems manageable, as long as a high proportion of the population is optimally vaccinated. Moreover, once $VE = 70\%$, the attack rate drop and full containment of the epidemic would be possible [9].

VACCINE DEVELOPMENT AND CLINICAL TRIALS

Despite many organizations have announced plans to start efficacy testing for their candidate vaccines, an approved vaccine is not expected until 2021, even with substantially compressed development timelines, smooth proceeding of clinical trials, and not accounting for possible failures [10]. Unlike typical therapeutics that are administered to sick patients, vaccines are intended for the healthy. Therefore, confirming the safety and effectiveness of a vaccine is of critical importance [11]. The two primary methods for demonstrating vaccine safety and efficacy are through either a vaccine efficacy randomized clinical trial (RTC) or a vaccine immunogenicity RTC. In the former, large numbers of recruited healthy volunteers are randomly selected to receive either the vaccine or a placebo and then monitored for some time. At the end of the surveillance period, the difference in the proportion of infections between the treatment and control arms is computed to demonstrate the ability of vaccine prevention. In a vaccine immunogenicity RCT, the primary endpoint is an immunity measurement or marker which is known to correlate with protection against infection or disease. This type of trial involves a smaller number of volunteers and requires a shorter follow-up period, and as a result, is quicker and less costly. Given that SARS-CoV-2 is a novel pathogen for which we do not yet know how to determine whether a subject is protected, vaccine efficacy must be confirmed using the longer and more costly vaccine efficacy RCT. Follow-up continues for all participants and includes a collection of serious adverse events for 6 months, and COVID-19 infection and multiple additional immunogenicity measurements through up to two years. Later phases of the study prioritize enrollment of more diverse populations, including those with chronic underlying health conditions and from racial/ethnic groups adversely affected by COVID-19 [12].

A human challenge trial (HCT), in which volunteers are randomized into either the vaccine or placebo arm and then infected deliberately with a live virus in a controlled setting, has been proposed as an alternative to accelerate the vaccine development process. Upon challenge, HCTs can quickly demonstrate the safety and efficacy of candidate vaccines in preventing infection or disease.

Depending on sample size, HCTs could also help to establish functional immune correlates of protection to inform the design of future vaccines. Since an HCT allows comparison of immune responses in vaccinated and unvaccinated individuals, precise measurements of post-vaccination viral loads, characterization of immune responses (innate, adaptive, cell-mediated) and antibody titers, and close monitoring and care of patients, it can help establish the correlates of protection and prove vaccine efficacy concurrently.

Moreover, a properly designed HCT can determine the transmission risk of the infected in a controlled setting with minimal exposure to investigators and the public.

While concerns have been raised regarding the ethics and morality of HCTs, it is generally accepted that HCTs are ethically permissible when the benefits to society outweigh acknowledged risks [13], and they have been deemed acceptable for developing vaccines for multiple infectious diseases such as influenza [14], malaria [15], typhoid [16], cholera [17], and dengue fever [18]. To the best of our knowledge, there have been no published studies of a quantitative analysis of the potential societal value of a COVID-19 HCT.

VACCINE TECHNOLOGIES AND TARGETS

RNA vaccine technology which has been preferred for vaccine candidates so far has enabled rapid vaccine development in response to this pandemic. RNA vaccines provide flexibility in the design and expression of vaccine antigens that can mimic antigen structure and expression during natural infection. RNA is required for protein synthesis, does not integrate into the genome, is transiently expressed, and is metabolized and eliminated by the body's natural mechanisms and, therefore, is considered safe. RNA vaccines for the prevention of infectious diseases and treatment of cancer have been shown in clinical trials to be safe and well-tolerated. In general, vaccination with RNA elicits a robust innate immune response. RNA directs expression of the vaccine antigen in host cells and has intrinsic adjuvant effects. A strength of the RNA vaccine manufacturing platform, irrespective of the encoded pathogen antigen, is the ability to rapidly produce large quantities of vaccine doses against a new pathogen. Most RNA vaccine candidates encode the receptor-binding domain (RBD) of the SARS-CoV-2 spike protein, a key target of virus-neutralizing antibodies [19]. Another well-known vaccine design strategy is incompetent virus vectors, which stabilized SARS-CoV-2 Spike (S) protein. These candidates are selected based on their immunogenicity and manufacturability profile. Vector vaccines are also used for Ebola, RSV, HIV, and Zika viruses [20].

COVID-19 VACCINE EFFECTS AND ADVERSE-EFFECTS

Phase III findings from ongoing vaccine trials being published, recently. Up to these results, after administration of prime and boost doses for RTCs, IgG concentrations, and SARS-CoV-2 neutralizing titers (in neutralization assays) in sera increased, TH1 skewed T cell immune responses with specific CD8⁺ and CD4⁺ T cell expansion. Interferon (IFN) γ was produced by a high fraction of specific CD8⁺ and CD4⁺ T cells. No serious adverse events were reported. Local injection site reactions and systemic events (mostly flu-like symptoms) were dose-dependent, generally mild to moderate, and transient. Symptoms such as fever, fatigue, chills, headache, muscle pain, joint pain, injection site pain, and tenderness occurred within 7 days after each dose. Reactogenicity resolved spontaneously or could be managed with simple measures (e.g. paracetamol). Whereas no relevant change in routine clinical laboratory values occurred after vaccination, temporary reduction of blood lymphocyte counts -related redistribution of lymphocytes into lymphoid tissues- and a transient increase in C-reactive protein (CRP) were observed in a dose-dependent manner in vaccinated participants. CRP is a well-known inflammatory serum protein previously

described as a biomarker for various infectious disease vaccines and an indicator of vaccine adjuvant activity [21].

CONCLUDING REMARKS

Immunization programs are only successful when there are high rates of acceptance and coverage. To accomplish this, it is critical to understand risk perceptions about COVID-19, acceptance of a COVID-19 vaccine, and confidence in media sources, specifically those used to obtain information about the COVID-19 pandemic. We must clearly understand the hesitancy and acceptance of a COVID-19 vaccine to develop evidence-based interventions. This will allow healthcare professionals and health officials to develop messaging to best address concerns and educate all people, especially vulnerable groups [22]. Since the beginning of the COVID-19 pandemic, our government has taken precautions, plans have been made, taken into account the risk that immunization services may be interrupted and there may be an increase in other vaccine-preventable diseases. Immunization is an indispensable part of the healthcare system and is carried out in our healthcare institutions without interruption following the COVID-19 pandemic period measures. Parents should follow the vaccination programs of their children, and when the vaccination time comes, they should contact family physicians and get information about vaccination practices. Children must be vaccinated during the COVID-19 pandemic, too. It has been reported by the World Health Organization that there are currently no known medical contraindications to vaccination of people with COVID-19, either. Also, studies show that the effect of mass influenza vaccination on the spread of COVID-19 and other influenza-like pathogens co-circulating during an influenza season [23]. Therefore, increasing influenza vaccine uptake, or enhancing the public health interventions, would facilitate the management of outbreaks of SARS-CoV-2 and other respiratory pathogens circulating during the peak flu season.

ABSTRACT

Coronaviruses are a family of enveloped RNA viruses that cause diseases in various mammals and birds. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a novel coronavirus identified as the cause of a global infectious disease called coronavirus disease 2019 (COVID-19). To date, there are currently no specific antiviral drugs that have been shown to effectively treat COVID-19. Moreover, vaccines based on viral-encoded peptides may not be effective against COVID-19, as virus mutations could make them futile. Many therapeutic strategies can be predicted in controlling and preventing the SARS-CoV-2 infections, such as oligonucleotide-based therapy, neutralizing monoclonal antibody therapy, autophagy pathway as therapeutic targets, chimeric antigen receptor T-cell (CAR-T) therapy, and mesenchymal-derived exosome therapy. Synthetic oligonucleotide-based therapeutic options containing small interfering RNA (siRNA) and antisense oligonucleotide (ASO) target the virus itself and mediate the silencing of its genome. Neutralizing monoclonal antibodies that target the receptor-binding motif (RBM) can prevent the virus from binding to angiotensin-converting enzyme 2 (ACE2), and are therefore promising antiviral drugs. On the other hand, vaccines and drugs can be developed to target the spike (S) glycoprotein of the coronavirus.

Autophagy plays an important role in viral infection. Autophagosomes can induce apoptotic cell death of virally infected cells and disrupt the virus replication cycle. CAR-T treatment is a successful therapeutic option for patients with relapsed and/or refractory hematologic malignancies. Increased interleukin-6 (IL-6) is related to cytokine storm

* Corresponding Author's Email: bbatar@nku.edu.tr.

syndrome (CSS) in COVID-19 patients. CAR-T therapy is used successfully in the blocking of IL-6. Therefore, IL-6 can be a specific target for CAR-T therapy in SARS-CoV-2 infected patients. Mesenchymal-derived exosomes demonstrate anti-inflammatory and immunomodulatory effects. MSC-derived exosomes can modulate the activity of T cells. MSC-derived exosomes may inhibit pro-inflammatory cytokines and increase the levels of anti-inflammatory cytokines such as IL-10 in SARS-CoV-2 infection. MSC-derived exosomes have been considered a specific therapeutic option for COVID-19 patients. Future preclinical and clinical investigations are needed to understand the critical roles of these therapy approaches in COVID-19.

Keywords: angiotensin-converting enzyme 2, autophagosomes, CAR-T, exosomes, monoclonal antibody, antisense oligonucleotide, SARS-CoV-2

INTRODUCTION

Therapeutic drugs affect molecular compounds, cellular pathways, and cellular processes for the treatment of diseases. Small molecule targets and peptides are the basic types of medical use.

RNA molecules containing antisense oligonucleotides (ASO) and small interfering RNAs (siRNA) are promising approaches for clinical trials [1]. These options can be used to inhibit and disrupt the virus RNA genome. Moreover, several mRNAs and microRNAs (miRNAs) are assessed for vaccination [2]. Besides, ribosomal RNA (rRNA)-targeted antibiotics are designed for the control of infections [3]. If these oligonucleotides are effectively delivered into the lungs, they can stop the infection.

Another promising option is neutralizing monoclonal antibodies that can be used as therapeutics. The major target of these agents is the viral spike (S) that mediates the binding of the virus to the angiotensin-converting enzyme 2 (ACE2) membrane receptor on the host cell. S1 subunit and S2 subunit are the two subunits of the viral S protein. The S1 subunit has two primary structural domains, receptor-binding domain (RBD) and N-terminal domain (NTD). The S2 subunit acts on virus-cell membrane interaction and fusion. Neutralizing monoclonal antibodies to the S protein provide immune protection against SARS-CoV and MERS-CoV [4, 5]. It is possible to produce efficacy humanized monoclonal antibodies. The SARS-CoV-2 infection could be prevented and treated by human monoclonal antibodies [6]. ACE2 receptor would be also created as an antibody-like molecule. For this strategy, a soluble form of the ACE2 receptor would bind to the S molecule of SARS-CoV-2 and neutralize the virus [7].

Coronaviruses can target the autophagy pathway and promote viral replication [8]. Stressful conditions upregulate autophagy. Autophagy provides cellular homeostasis and involves the organization of numerous molecules. These molecules are generally called autophagy-related (ATG) proteins. Autophagosome formation is a major process for the canonical autophagy pathway. Autophagosome fuses with the lysosome and performs enzymatic degradation.

Autophagy plays a role in regulating pathogen degradation mechanisms. Thus, autophagy is a major part of the immunity against pathogens, such as viruses.

Severe COVID-19 patients have elevated serum levels of IL-6. Increased IL-6 plays a key role in cytokine storms. Chimeric antigen receptor T-cell (CAR-T) immunotherapy appears to control and prevent cytokine storms in SARS-CoV-2 infected patients [9].

Exosomes contain several molecules such as mRNAs, tRNAs, proteins, and microRNAs (miRNAs). Mesenchymal-derived exosomes exhibit immunomodulatory and anti-inflammatory responses. Molecular components of exosomes can regulate immune reactions [10]. Thus, in COVID-19, mesenchymal-derived exosomes can be used as a therapeutic option.

Many drugs are known for clinical evaluation of COVID-19. However, more attention has been paid to these treatment strategies.

OLIGONUCLEOTIDES AS THERAPEUTIC DRUGS

In recent years, it has been made promising progress in the understanding of viral genomics and target-based drugs have been designed for silencing viral gene expression as new therapeutic approaches. Oligonucleotide-based therapeutics have significant anti-viral properties [11]. Oligonucleotide-based therapies, such as ASOs and siRNAs neutralize the viral mRNA molecules.

ASOs are single-stranded DNA or RNA molecules. These oligonucleotides are approximately 15-20 nucleotides in length. ASOs bind to target mRNA and block its function or gene transcription. ASOs have been commonly used in the studies of gene functions and the development of new therapeutics [12]. ASO was first used to block HIV replication [13]. Treatment on ASO strategy requires knowledge of the DNA sequence. Therefore ASOs would be improved against the SARS-CoV-2 DNA sequence and block viral infection.

siRNA also called short interfering RNA or silencing RNA is a double-stranded non-coding RNA molecule. siRNA is approximately 20-25 base pairs in length. Gene expression can be regulated by siRNAs. siRNA-based therapeutic molecules have been designed and applied for antiviral diseases [14]. siRNA-mediated treatment can be an effective option for combating with COVID-19.

The SARS-CoV-2 viral genome is approximately 30 kb long. This genome consists of fourteen open reading frames (ORFs) and codes twenty-seven structural and nonstructural proteins [15]. Ribosome translates ORF1a and ORF1b into a single large poly-protein. The ORF1a contains two viral cysteine proteases, papain-like protease (nsp3) and 3-chymotrypsin-like protease (3CL). The sequence in which codes the nsp3 has been less conserved, however sequence which codes the protease 3CL (nsp5) has been highly conserved. In recent, the protease has been a major drug target for multiple antiviral pathogens. Thus, the nsp5 coding sequence can be treated as a potential target for siRNA-based therapeutics.

Viral RNA dependent RNA polymerase (Rd-Rp) is the other possible target. Rd-Rp is located in the ORF1b and encompasses 13-16 kbp on the viral genome. Rd-Rp site is a highly conserved genome of SARS-CoV-2. Therefore, this region can be evaluated as a potential target for siRNA.

Currently, nanoparticles based carriers and viral vectors have been used as delivery systems for siRNA. In 2003, a siRNA drug was developed targeting SARS-CoV and H5N1

influenza genome by Sirnaomics, Inc. (Maryland, USA). Furthermore, in 2017, Alnylam Pharmaceuticals (USA) and Vir Biotechnology have developed six siRNA against infectious diseases [16]. Nevertheless, more effective carriers should be identified for the targeted specific delivery of the drug.

MECHANISMS RELATED TO CELL ENTRY OF SARS-CoV-2 AS THERAPEUTIC TARGETS

The scientific community has little knowledge of the molecular pathogenesis of SARS-CoV-2. Viruses must enter host cells before they can initiate their life cycle. Therefore, one of the critical steps for the development of effective therapeutics for COVID-19 is to clearly understand the exact mechanism of how the virus enters the human body. The majority of viruses have developed strategies to invade the cell by a process called receptor-dependent endocytosis [17]. Knowledge about the receptor recognition mechanisms of coronaviruses is critical for the development of targeted antiviral treatments focused on blocking that pathway. The cell entry mechanism of SARS-CoV-2 has been extensively studied.

The crown-like appearance of coronaviruses is caused by spike proteins, which are necessary for the viruses to enter the target cell by endocytosis. Three spike proteins assemble into trimers on the virus surface to form a crown-like appearance. The SARS-CoV-2 coronavirus uses a spike protein to bind to the ACE2 receptor on the cell surfaces. Therefore, the distribution and expression of ACE2 may be critical for the target organ of the SARS-CoV-2 [18].

The spike protein is composed of two subunits; S1 and S2. The S1 subunit contains two distinctive domains, the N-terminal domain, and the C-terminal domain. These domains of the S1 subunit can function as receptor-binding domains (RBD). The S2 subunit is the most conserved region of the protein and responsible for mediating membrane fusion between the virus and the host cell membrane. After the spike protein of SARS-CoV-2 binds to ACE2 through its RBD, the S protein priming, allowing the fusion of viral and cellular membranes and viral entry into the cell is done by a protease enzyme [19]. Recent studies revealed that the transmembrane serine proteinase 2 (TMPRSS2), furin, trypsin, and elastase prime the S proteins and provided evidence that successive S protein cleavage at two sites is required for S protein priming. After cleavage, the spike protein S1 segment remains attached to ACE2, while the spike protein S2 segment anchors the viral and cellular membranes, inducing fusion, and viral entry [20].

The ACE2/SARS-CoV-2 complex undergoes endocytosis, which is typically mediated by the acidic endosomal pH, resulting in the fusion of the viral and endosomal membranes and release of the viral genome into the cytosol for productive infection. The results revealed that the cellular entry of SARS-CoV-2 is through clathrin-mediated endocytosis [17].

This discovery is important in the search for several inhibitors targeting the endocytic pathway including endosome and lysosome in the treatment of COVID-19. Several inhibitors targeting the endocytic pathway appear to have therapeutic potential including lysosomotropic agents, clathrin-mediated endocytosis inhibitors, and endosomal/lysosomal protease inhibitors [21].

Chloroquine and hydroxychloroquine, often in combination with a second-generation macrolide, are probably the most well-studied lysosomotropic agent that accumulates in the acidic organelles such as endosomes and lysosomes and neutralizes their pH. They have widely used malaria drugs that have yielded mixed results for the treatment of COVID-19.

Chlorpromazine (CPZ) inhibits membrane fusion processes on clathrin-dependent endocytosis and thereby prevents the entry of the virus into host cells [21]. Therefore, it can be used for the treatment of COVID-19. The inhibition of SARS-CoV-2 by CPZ was suggested in an in vitro study using cell lines. The first clinical study on the treatment of COVID-19 of CPZ has started in Paris. The results in this study suggest that CPZ is unlikely to have the therapeutic potential in the treatment of COVID-19 [22].

Cathepsins are endosomal and lysosomal proteases that play important roles in various cellular processes including both the endocytic pathway and autophagy. Several studies suggested that the inhibitors of cathepsin proteases such as teicoplanin acts to inhibit entry of the virus [23].

The endocytosis route of SARS-CoV-2 involves key proteins involved in endosome formation. The phosphatidylinositol 3-phosphate 5-kinase (PIKfyve) synthesizes a class of phosphoinositides that are required in the maturation process of endosomes. The activity of PIKfyve has been discovered to be essential in the SARS-CoV-2. Apilimod and Vacuolin-1, small molecule inhibitors of PIKfyve were found to significantly reduce SARS-CoV-2 entry. These results suggest the potential for targeting PIKfyve in developing new antiviral molecules against SARS-CoV-2 [24].

The other target is proton pumps that drive protons into endosomes and lysosomes, lowering the pH. Thus, the acidic environment that is required for pH-dependent protease activity is provided. Zohreh et al. hypothesized that metformin may be an effective treatment of COVID-19-related pulmonary fibrosis because it a potential regulator of Vacuolar ATPase and endosomal Na^+/H^+ exchangers, and additionally a regenerative agent for lung fibrosis [25].

Two pore segment channel 2 (TPC2) is a calcium release channel expressed in lysosomal membranes. An article by Ou et al. demonstrated that the activity of human TPC2 is a key player for SARS-CoV-2 cell entry [24]. They suggested that the blocking TPC2 activity by tetrandrine, an inhibitor for TPC2, decreased entry of SARS-CoV-2 S pseudovirions.

SARS-CoV-2 cell entry depends on ACE2 and TMPRSS2. TMPRSS2 is a member of transmembrane protease serines, which are a family of proteins with conserved serine protease domains located on the cell membrane. TMPRSS2 is expressed by human lung cells. Therefore, it is thought that TMPRSS2 plays an important part in virus entry into respiratory system cells. Also, TMPRSS2 happens to be present near the spike-ACE2 binding interface. This cleavage must occur after spike S1 Subunit -ACE2 binding. If it occurs before, the virus is less able to infect the cell. TMPRSS2 inhibitors (Nafamostat, Bromhexine, Aprotinin, Camostat) play a key role in the treatment of COVID-19 disease. The protease inhibitor camostat mesylate is already in clinical use for the treatment of pancreatitis. It was known to inhibit TMPRSS2 and effectively protected the mice against death caused by SARS-CoV infection [26].

SARS-CoV-2 has a high binding capacity for ACE2 – between 10-20 times more than the original coronavirus. This means it is much easier for SARS-CoV-2 to get into human cells compared to the original coronavirus. The structures of SARS-CoV-2 RBD that are essential for ACE2 binding showed that it contains a core and an RBM. The RBD is the most

immunogenic region of COVID-19 spike protein and contains major neutralization epitopes, which induce most of the host immune responses [24]. Therefore, these epitopes may serve as subunit vaccines against coronavirus infections. Therefore, it presents a major challenge to both vaccination and antibody-drug. A structure-based strategy for SARS-CoV-2 RBD may help design subunit vaccines. The hot spot residues at the SARS-CoV-2 RBM are important for SARS-CoV-2 binding to ACE2 receptors.

Monteil et al. suggested that human recombinant soluble ACE2 can significantly block the early stages of SARS-CoV-2 infections in artificial human tissues [27]. Thus, an antibody-drug with a significantly higher RBD binding affinity than ACE2 can block viral attachment. On the other hand, vaccines and drugs can be developed to target the S2 subunits of the spike glycoprotein of the coronavirus. However, the success of this approach may be limited because the spike S2 subunit is less immunogenic than the SARS-CoV-2 Spike S1 protein RBD.

Another potential drug target might be the cellular enzymes that attach fatty acids to a cluster of cysteines in the cytoplasmic tail of spike protein. However, enzymes that attach acyl chains to S have not been identified.

AUTOPHAGY PATHWAY AS THERAPEUTIC TARGETS

Autophagy is conserved in all eukaryotic cells. Autophagy is a constitutive pathway, also it is activated by endoplasmic reticulum stress, starvation, and pathogen infections. Autophagy involves the formation of autophagosomes. Autophagosomes enclose cytoplasmic components, such as protein aggregates and organelles. Furthermore, autophagosomes deliver these components to lysosomes for degradation. Therefore, autophagy is one of the major degradation pathways.

The autophagy pathway is regulated by several proteins encoded by autophagy-related genes (ATGs). The autophagy process is performed through many stages. First, class III phosphatidylinositol 3-kinase (PtdIns3K) protein complex forms autophagy-specific phagophore. Second, the ULK complex expands the phagophore. Also, the Atg8 protein family matures the phagophore. Then, cytoplasmic components are recruited through autophagic receptors followed by the fusion of vesicles with endosomes. The vesicle-endosome complex is called as amphisome. Last, amphisome fuses with a lysosome and subsequently, degradation occurs.

Coronaviruses like other RNA viruses stimulate the development of double-membrane vesicles (DMVs), a hallmark of autophagy [28]. These vesicles mimic autophagosomes. The fusion of viral DMVs with lysosomes (also with late endosomes) results in viral acidification which induces viral replication or virion maturation [29]. Some coronaviruses release their genome into the cytoplasm of the host cell during the entry of the virus [30]. SARS-CoV replicates and transcribes its genome through the autophagic pathway.

The fusion of DMV-lysosome is a crucial stage in the autophagy pathway. The fusion between the autophagy pathway and DMVs may occur during the life cycles of coronaviruses [31]. Coronavirus DMVs play a role as the RNA synthesis site for coronaviruses [32].

Chloroquine, an anti-malarial drug, is a lysosomotropic agent. It neutralizes endosomes and lysosomes. Chloroquine mainly blocks the autophagic pathway by impairing

autophagosome fusion with the lysosome and inhibits the lysosomal degradation activity [33]. The acidic subcellular compartments, lysosomes, and endosomes, are neutralized by chloroquine. Besides, chloroquine can stimulate autophagy-independent dysfunctions of endosomal-lysosomal systems. Thus, chloroquine may affect on the fusion between autophagosome and lysosome [33].

It is well known that chloroquine has anti-viral effects, such as anti-CoVs, anti-HIV, and anti-influenza [34]. It has been suggested that chloroquine treatment suppressed the viral infection in SARS-CoV-infected Vero E6 cells [35]. Also, a recent study revealed that chloroquine inhibits the SARS-CoV-2 infection in Vero E6 cells [36]. In another study, chloroquine has been tested for COVID-19 treatment. The first evidence on in vitro assay showed that they could act on anti-SARS-CoV-2 [37].

The mechanisms of the chloroquine effect are not known clearly during SARS-CoV2 infection. Also, the clinical efficacy of chloroquine is unclear and needs further studies.

Autophagy regulates innate and adaptive immunity. Activation of autophagy can induce the immune system [38]. Targeting the immune system, such as autophagy that regulates immunity could be a therapeutic approach against SARS-CoV-2 infection.

A viral-infected body encounters infection through the innate immune system also the adaptive immune responses are carried out by recruiting virus-specific T lymphocytes and B lymphocytes, respectively. Cell-mediated and humoral immune responses are stimulated. These immune responses both potentiate inflammatory effects and neutralize against viral invasion.

Macrophages and dendritic cells, antigen-presenting cells (APC), present the viral antigen to T cells through human leukocyte antigen (HLA). Activated T cells are transformed into CD8 + T cells and CD4 + T cells. These cells activate both cell-mediated and humoral immune responses. CD8 + T cells disrupt virus-infected cells. CD4 + T cells play a pivotal role in priming CD8 + T cells and B cells. Th1 cells, one of the subsets of CD4+, both stimulate natural killer (NK) cells and CD8 + T cells or remain as memory T cells. However, CD4 + Th2 cells activate B cells to be converted into plasma B cells. Then, B cells produce SARS-CoV-2-specific IgM and IgG antibodies [39]. These antibodies bind and neutralize SARS-CoV-2. Many B cells form immune memory.

Some of the viruses block autophagy by inhibiting autophagy-inducing pathways, AKT1/BECN1, to stimulate viral replication [40]. A recent study has confirmed that SARS-CoV-2 infection also inhibited autophagy [41]. Also, this study suggested that autophagy stimulation revealed the potentiality against this infection [41].

Fasting activates autophagy [42], which induces immunity [43]. Therefore, fasting may control and prevent to COVID-19 [44]. However, to date, there is no experimental evidence that determined the effects of fasting against SARS-CoV-2 infection.

CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPEUTIC STRATEGY FOR COVID-19

T cells play a key role in the initiation of antiviral immune responses. Investigations in lymphocytes of COVID-19 patients are beginning to emerge [45]. Lymphopenia is one of the

major hallmarks of severe COVID-19. T cells, B cells, and natural killer (NK) cells are affected by lymphopenia [46]. It has been demonstrated that SARS-CoV-2 has an impact on T cell function [47]. Patients with severe COVID-19 are most likely to have a reduced number of lymphocytes, monocytes, eosinophils, and basophils. COVID-19 patients have decreased Th cell counts and suppressor T cell counts. These findings show the importance of the T cell-based immunotherapies for COVID-19.

Immunotherapy has promising success in cancer, autoimmune diseases, and other immune system-related diseases [48, 49]. Immunotherapy can be accepted to improve immune responses in COVID-19. It has been well known for the success of interferons in viral infections, so several studies investigate the efficacy of interferon-alpha-1b and alpha-2b for the treatment of COVID-19 [47].

Chimeric antigen receptor T-cell (CAR-T) immunotherapy, adoptive cell therapy, is extensively used for the treatment of patients with hematologic malignancies due to their immune dysregulation and long-term immune reconstitution. Current, CAR-T cell therapy has made promising progress in the treatment of refractory and/or relapsed (R/R) hematological malignancies. Targeting the CD19 CAR-T cell therapy has shown efficient remission in non-Hodgkin lymphoma (NHL) and acute lymphocytic leukemia (ALL) [50].

Importantly, antigen-specific T cells were developed against chronic viral infections. HBV-specific T cells were renewed by CAR-T cells [51]. Böhne et al. first produced CAR-T cells targeting the hepatitis B surface antigen (HBsAg). CAR-T cells were developed to recognize a determinant of HBsAg and to direct aa37-43 in the preS1 peptide. Thus, HBsAg-positive primary human hepatocytes were able to target, and specifically, HBV-infected target cells were eliminated [52]. HIV-targeted CAR-T cells have been generated for the treatment of HIV/AIDS. In recent years, anti-HIV neutralizing antibodies (bNAbs), and bNAb-based CAR-T therapy has been developed as a potential treatment strategy to control HIV infection [53].

To date, numerous immune cell-based immunotherapeutic options against SARS-CoV-2 are being significantly improved. A study demonstrated that CAR-NK cells may have the potential to treat patients with severe COVID-19 [54]. NK cells are extracted from peripheral blood and can be modified to express CAR.

NK cell therapy has a significant anti-tumor effect, which is the direct activity of NK cells on the immune system [55]. Thus, COVID-19, a viral infection associated with immune dysregulation, can be treated with regenerative medicine and its immunoregulatory actions [56].

COVID-19 patients exhibit increased serum inflammatory cytokines. Interleukin-6 (IL-6) seems to play an important role in COVID-19 associated cytokine storm syndrome (CSS). Based on the successful use of IL-6 receptor blockade for CAR-T cell therapy-related cytokine release syndrome (CAR T-cell CRS), similar strategies using tocilizumab, an anti-IL-6 receptor antibody, are being investigated in COVID-19 [9].

CAR-T immunotherapy might be considered for severe COVID-19 patients at increased risk of complications. If patients are affected by hematological diseases and are suffering from relapsed and/or refractory diseases, CAR-T might be useful to control SARS-CoV-2 infection [57].

MESENCHYMAL STEM CELLS-DERIVED EXOSOMES IN COVID-19 TREATMENT

Cell-based therapies aim to control or prevent the damage and disease by repairing and/or replacing the injured cells and tissues. Also, many cell-based therapies contribute to stopping degenerative and pathophysiologic progress [58].

Mesenchymal stem cell (MSC) treatment is one of the major therapy among stem cell-based therapies. MSCs are widely used in regenerative medicine. These cells can repair damaged tissues and organs. Also, MSCs have anti-apoptotic, anti-inflammatory, pro-inflammatory immune reactions. MSCs regulate the immune responses through the transforming growth factor b1 (TGF β 1), which can stimulate the Treg proliferation, activate IL-6, which inhibits the neutrophil proliferation, and induce the prostaglandin E2 (PGE2), which prevents the antigen presentation by dendritic cells and T-effector cell proliferation [59, 60]. MSCs play an important role in immunomodulatory activity [61]. These features have revealed that MSCs are clinically significant.

MSC treatment has been effectively applied to treat many disorders such as degenerative, inflammatory, and metabolic diseases. Furthermore, MSCs are used for cancer therapy. Moreover, Recently, it has been suggested that the transplantation of MSCs enhanced the pulmonary function of COVID-19 patients [62]. Many reports revealed that MSC treatment is associated with low mortality and morbidity rates in COVID-19 patients [63]. The MSCs could use in immunomodulatory effects and differentiation potency for the COVID-19 treatment [64]. MSC treatment of COVID-19 patients is limited.

The exosomes are released from all types of cells, including stem cells [65]. The exosomes are membrane-enclosed extracellular vesicles (EVs). The exosomes include several molecules, such as miRNAs, tRNAs, long noncoding RNAs (lncRNAs), growth factors, proteins, and lipids. Molecular structures of exosomes can affect the immune regulations and epigenetic alterations [10]. Exosomes can be used as promising therapeutic approaches.

MSC-derived exosomes can be useful for repairing damaged tissues and organs. MSC-derived exosomes provide several advantages in comparison to traditional cell-based therapies. MSC-derived exosomes are safer and more stable than cells [66]. In addition to these advantages, MSC-derived exosomes increase their therapeutic potential, exosomes could be modulated with several types of cargos, such as mRNA, miRNA, and proteins [67].

MSC-derived exosomes can modulate the function of T cells. It has been found that MSC-derived exosomes treatment both enhanced the interleukin-10 (IL-10) and TGF- β 1 expression levels, therefore the function of immunosuppressive regulatory T cells increased [68]. Moreover, MSC-derived exosomes reduced the levels of inflammatory cytokines, eosinophils, infiltrated mast cells, IgE, and CD86+ and CD206+ cells [69].

Many infected COVID-19 patients have a multiorgan injury. MSC-derived exosomes are known to reduce lung injury in asthmatic models and acute respiratory distress syndrome (ARDS) [68, 70]. Thus, Organ and tissue damage related to COVID-19 can be treated by MSC-derived exosomes.

Preclinical and clinical findings support the investigational MSC-derived exosomes application due to their anti-inflammatory and immunomodulatory abilities. MSC-derived exosomes can be a useful treatment strategy to reduce the effect of SARS-CoV-2 infection.

CONCLUSION

Currently, no therapeutic approach is approved for COVID-19. The development of diverse therapeutic strategies directing SARS-CoV-2 is needed for the treatment of patients with COVID-19. Oligonucleotide-based therapy, neutralizing monoclonal antibody therapy, autophagy pathway as therapeutic targets, chimeric antigen receptor T-cell (CAR-T) therapy, and mesenchymal-derived exosome therapy are novel therapeutic options against SARS-CoV-2 infection. The use of biomolecules associated with these novel therapeutics can provide significant results for the treatment of COVID-19 patients.

Chapter 472

OVERVIEW OF U.S. DOMESTIC RESPONSE TO THE 2019 NOVEL CORONAVIRUS (2019-nCoV)*

***Sarah A. Lister, Frank Gottron, Kavya Sekar,
Audrey Singer and Agata Dabrowska***

BACKGROUND

On December 31, 2019, the World Health Organization (WHO) was informed of a cluster of pneumonia cases in Wuhan City, Hubei Province of China.¹ Illnesses have since been linked to a previously unidentified strain of coronavirus, designated 2019 Novel Coronavirus, or 2019-nCoV. As of February 7, 2020, tens of thousands of people have been infected and over 500 have died, mostly in China.² The disease has spread to several other countries, including the United States.

On January 30, 2020, the Emergency Committee convened by the WHO Director-General declared the 2019-nCoV outbreak to be a Public Health Emergency of International Concern (PHEIC).³ The next day, on January 31, 2020, U.S. Department of Health and

³ WHO, “Statement on the second meeting of the International Health Regulations (2005) Emergency Committee regarding the outbreak of novel coronavirus (2019-nCoV),” January 30, 2020, [https://www.who.int/news-room/detail/30-01-2020-statement-on-the-second-meeting-of-the-international-health-regulations-\(2005\)-emergency-committeeregarding-the-outbreak-of-novel-coronavirus-\(2019-ncov\)](https://www.who.int/news-room/detail/30-01-2020-statement-on-the-second-meeting-of-the-international-health-regulations-(2005)-emergency-committeeregarding-the-outbreak-of-novel-coronavirus-(2019-ncov)). A PHEIC is defined in the IHR (2005) as “an extraordinary event which is determined, as provided in these Regulations: i) to constitute a public health risk to other States through the international spread of disease; and ii) to potentially require a coordinated international response.” This definition implies a situation that is serious, unusual or unexpected; carries implications for public health beyond the affected State’s national border; and may require immediate

Human Services (HHS) Secretary Alex Azar declared the outbreak to be a Public Health Emergency pursuant to Public Health Service Act (PHSA) Section 319, retroactively dated to January 27, 2020.⁴

As the scope of the epidemic widens in China, as of early February, U.S health officials continue to state that the immediate health risk from the new virus to the general American public is low.⁵ With the situation rapidly changing, both WHO and the U.S. Centers for Disease Control and Prevention (CDC) post frequent updates.⁶

The Response to 2019 Novel Coronavirus: Status as of February 6, 2020

International: Selected World Health Organization (WHO) Declarations

<https://www.who.int/emergencies/diseases/novel-coronavirus-2019>

- January 22, 2020: WHO Director-General convened Emergency Committee for Pneumonia due to the Novel Coronavirus 2019-nCoV, which agreed on the “urgency of the situation” but did not declare it a Public Health Emergency of International Concern (PHEIC).
- January 30, 2020: The Emergency Committee convened by the WHO Director-General declared the 2019-nCoV outbreak to be a PHEIC.

Domestic: Selected Events and United States Government Actions

<https://www.hhs.gov/about/news/index.html>; <https://www.cdc.gov/coronavirus/2019-nCoV/summary.html>;
<https://travel.state.gov/content/travel/en/traveladvisories/ea/novel-coronavirus-hubei-province—china.html>; and
<https://www.fda.gov/emergency-preparedness-and-response/mcm-issues/novel-coronavirus-2019-ncov>.

- January 7, 2020: CDC established a 2019-nCoV Incident Management Structure.
- January 21, 2020: First travel-related case of 2019-nCoV detected in the United States.
- January 21, 2020: CDC activated its Emergency Operations Center to better provide ongoing support to the 2019-nCoV response and issued updated travel guidance for China, recommending that travelers avoid all nonessential travel to all of the country.
- January 23, 2020: U.S. Department of State ordered the departure of all nonemergency U.S. personnel and their family members from Wuhan.
- January 29, 2020: President Donald Trump announced the formation of the President’s Coronavirus Task Force, led by HHS and coordinated by the National Security Council.
- January 29, 2020: State Department allowed for the voluntary departure of nonemergency personnel and family members of U.S. government employees from China.
- January 30, 2020: First U.S. person-to-person transmission of 2019-nCoV.
- January 30, 2020: State Department updated the Travel Advisory for China from a Level 3: Reconsider Travel to Level 4: Do Not Travel due to novel coronavirus first identified in Wuhan, China.
- January 31, 2020: U.S. Department of Health and Human Services (HHS) Secretary Alex Azar declared the outbreak to be a Public Health Emergency pursuant to Public Health Service Act (PHSA) Section 319.
- January 31, 2020: President Trump issued a proclamation that suspends the entry of any foreign national who has been in China within the prior 14 days, subject to some exceptions.
- February 2, 2020: Travel restrictions and additional quarantine requirements on travelers from China went into effect.
- February 3, 2020: CDC submitted an Emergency Use Authorization (EUA) package to the U.S. Food and Drug Administration (FDA) for the 2019-nCoV diagnostic test—Real-Time RT-PCR Diagnostic Panel.
- February 4, 2020: FDA issued an EUA enabling emergency use of CDC’s Real-Time RT-PCR Diagnostic Panel, permitting CDC to share diagnostic kit with other labs.

international action. See WHO webpage on PHEIC at <https://www.who.int/ihr/procedures/pheic/en/>, accessed on January 31, 2020.

⁴ U.S. Department of Health and Human Services (HHS), “Secretary Azar Declares Public Health Emergency for United States for 2019 Novel Coronavirus,” press release, January 31, 2020, <https://www.hhs.gov/about/news/2020/01/31/secretary-azar-declares-public-health-emergency-us-2019-novel-coronavirus.html>.

⁶ WHO, “Novel Coronavirus (2019-nCoV) Situation Reports,” <https://www.who.int/emergencies/diseases/novel-coronavirus-2019/situation-reports>; and U.S. Centers for Disease Control and Prevention (CDC), “2019 Novel Coronavirus (2019-nCoV) Situation Summary,” <https://www.cdc.gov/coronavirus/2019-ncov/summary.html>.

This report discusses selected actions taken by the federal government to quell the introduction and spread of 2019-nCoV in the United States. The HHS Secretary has taken several specific actions to address the 2019-nCoV threat. While some of these actions are based in generally applicable authorities of the Secretary, other authorities may be contingent upon the Secretary or another federal official making a determination or declaration, specific to that authority, regarding the existence of a public health emergency or threat. Each of the actions taken by the Secretary, its statutory basis, and any distinct declarations and determinations supporting the action is presented in this report.

Additional CRS products about this outbreak may be found on the “2019 Novel Coronavirus” Hot Topics tab at www.crs.gov/.

2019 NOVEL CORONAVIRUS (2019-nCoV)

Coronaviruses (see Figure 1) are common respiratory pathogens, usually causing mild illnesses such as the common cold; however, several strains that cause serious illness have emerged in recent years. 2019-nCoV is causing the third serious outbreak of novel coronavirus in modern times, following severe acute respiratory syndrome (SARS) in 2002 and Middle East Respiratory Syndrome (MERS) in 2012.⁷ The global health community is closely monitoring 2019-nCoV because of the severity of symptoms (including death) among those infected and the speed of its spread worldwide. Experts do not know the origin of 2019-nCoV, though genetic analysis and other features suggest an animal source.⁸

⁸ Jon Cohen, “Mining Coronavirus Genomes for Clues to the Outbreak’s Origins,” *Science*, January 31, 2020, <https://www.sciencemag.org/news/2020/01/mining-coronavirus-genomes-clues-outbreak-s-origins>; and CDC, “2019 Novel Coronavirus (2019-nCoV) Situation Summary,” updated February 3, 2020, <https://www.cdc.gov/coronavirus/2019-nCoV/summary.html>.

Health officials and researchers are still learning about 2019-nCoV. According to CDC, 2019-nCoV typically causes respiratory infections characterized by a fever, cough, and sometimes breathing difficulty—a suite of symptoms that is common during influenza season.⁹ Features that have yet to be clarified include routes of transmission (e.g., through the air, from contaminated surfaces); the incubation period (the time between infection and the onset of symptoms); and whether an infected person without symptoms can transmit infection.¹⁰ Although it was first reported that 2019-nCoV infections resulted from an animal contact, Chinese officials confirmed person-to-person transmission on January 21, 2020.¹¹ Chinese officials have also reported transmission of the virus from asymptomatic patients.¹² However, this finding has yet to be confirmed by U.S. and international health officials and other experts. While WHO and other health experts acknowledge transmission among asymptomatic individuals is possible, scientists agree that asymptomatic transmission is unlikely to be a driver of the outbreak.¹³

At this time no specific treatment or preventive vaccine exists for 2019-nCoV infections. Care for patients is supportive: maintaining hydration, preventing secondary infections, and providing respiratory support, such as use of a ventilator, if needed.¹⁴

DOMESTIC RESPONSE

In the United States, communicable disease control involves collaboration among federal agencies, state health departments, and international partners. Authority to compel isolation (for sick patients), quarantine (for healthy exposed persons), and disease reporting generally rests in state law.¹⁵ The HHS Secretary and, by delegation, CDC have broad authority to assist in the control of communicable diseases through international cooperation, federal-state cooperation, and public health emergency response activities.¹⁶ In addition, CDC (by delegation) has explicit authority to detain, examine, and release persons arriving into the United States, and traveling between states, who are suspected of having a communicable

disease.¹⁷ Other authorities, such as those in the Immigration and Nationality Act of 1952 (INA, P.L. 82-414), allow for other actions relevant to communicable disease control, such as travel restrictions.¹⁸

The use of federal and state disease control authorities and other key actions taken in response to the 2019-nCoV outbreak are discussed below. These activities of federal agencies in collaboration with state and local governments include, among others (1) investigation of 2019-nCoV cases and infection control measures in the community, (2) travel restrictions and/or quarantine requirements on certain travelers who have recently visited China, (3) medical countermeasure development, and (4) health system preparedness. Federal agencies involved include several HHS agencies, such as CDC, the Assistant Secretary for Preparedness and Response (ASPR), the National Institutes of Health (NIH), and the U.S. Food and Drug Administration (FDA), in collaboration with other agencies such as the U.S. Department of State and the Department of Homeland Security (DHS).

Investigation and Control of 2019-nCoV Cases in the Community

To curb the spread of 2019-nCoV cases in the community, state, tribal, and local health departments, with support from CDC, work to identify cases, investigate the possible spread of disease, and take infection control measures.

Case identification begins with testing for 2019-nCoV. CDC urges clinicians to consider a patient's travel and/or contact history and a 14-day incubation period when deciding whether to inform health departments and obtain patient specimens (e.g., mucus, urine) for 2019-nCoV testing. Health care providers are urged to report possible cases to state, tribal, and/or local health departments, which then report to CDC.¹⁹

CDC has developed a diagnostic test for the 2019-nCoV virus and initially performed all domestic testing on suspected patients.²⁰ On February 5, 2020, CDC announced that it would begin distributing test kits to state and local laboratories, following an authorization from the FDA (see the "Medical Countermeasures" section for more details).²¹ CDC has been facilitating the collection and transport of specimens until the diagnostic test is made locally available.²²

Once a patient is reported and in the process of having specimens tested, he or she is considered a *patient under investigation* (PUI) for 2019-nCoV. CDC has developed guidelines for isolation and other precautions for PUIs (including potential PUIs) or those

receiving supportive care for 2019-nCoV infection in healthcare settings.²³ A key goal of the guidelines is the prevention of disease transmission to health care workers, who may be exposed through high-risk procedures, such as maintaining an ill patient on a ventilator.²⁴

Disease investigation for confirmed cases involves *contact tracing*—identifying and evaluating individuals who had contact with the patient to determine if transmission has occurred. These investigations are generally conducted by state, tribal, and local health officials, often with support and technical assistance from CDC.²⁵ As of February 3, 2020, CDC has reported two U.S. cases of person-to-person transmission of 2019-nCoV among close household contacts and has indicated that it expects to find additional cases of person-to-person transmission.²⁶

As of February 3, 2020, CDC reported that it had “deployed multidisciplinary teams to Washington, Illinois, California, and Arizona to assist health departments with clinical management, contact tracing, and communications.”²⁷ In addition, the Public Health Emergency Declaration by Secretary Azar, pursuant to PHSA Section 319, gives state, local, and tribal health departments more flexibility to reassign personnel to respond to 2019-nCoV if their salaries are funded in whole or in part by PHSA authorized programs.²⁸

Travel Restrictions and Quarantine Requirements

Restrictions and Requirements in Effect

CDC and the U.S. Department of State have issued advisories to avoid unnecessary travel to China, including a rare Level 4 advisory from the State Department to avoid all travel to China.²⁹ In addition, the Trump Administration has imposed entry restrictions and quarantine requirements in response to the entry of individuals who may pose a risk of introducing the 2019 Novel Coronavirus into the United States.

With respect to entry restrictions, President Trump issued a proclamation on January 31, 2020, that suspends the entry of any foreign national who has been in China within the prior 14 days, subject to some exceptions.³⁰ The exceptions cover lawful permanent residents

³⁰ The White House, “Proclamation on Suspension of Entry as Immigrants and Nonimmigrants of Persons Who Pose a Risk of Transmitting 2019 Novel Coronavirus,” January 31, 2020, <https://www.whitehouse.gov/presidential-actions/proclamation-suspension-entry-immigrants-nonimmigrants-persons-pose-risk-transmitting-2019-novel-coronavirus/>.

(LPRs), most immediate relatives of U.S. citizens and LPRs, and some other groups.³¹ The proclamation directs the Department of State and the Department of Homeland Security (DHS) to establish procedures for implementing and enforcing the entry restrictions, which by the terms of the proclamation took effect at 5:00 p.m. (EST) on February 2, 2020. For statutory authority, the proclamation relies principally upon Section 212(f) of the INA.³² That statute authorizes the President “to suspend the entry of all aliens or any class of aliens” whose entry he “finds ... would be detrimental to the interests of the United States.”³³ The Supreme Court has held that Section 212(f) “exudes deference to the President” and gives him mostly unfettered discretion to decide “when to suspend entry,” “whose entry to suspend,” “for how long,” and “on what conditions.”³⁴ The presidential proclamation is in effect until terminated by the President.³⁵ The proclamation also directs the HHS Secretary to “recommend that the President continue, modify, or terminate this proclamation.”³⁶ Such recommendation is required “no more than 15 days after the date of this order and every 15 days thereafter.”³⁷

Quarantine requirements also went into effect on February 2, 2020, according to a DHS announcement.³⁸ All persons, including U.S. nationals, LPRs, and their immediate families who arrive in the United States within 14 days after having been in China are to arrive and be screened at one of 11 designated arrival airports, and such persons may be subject to mandatory quarantine, pursuant to the standing quarantine authorities of the HHS Secretary under PHSA Section 361.³⁹ Persons showing symptoms of illness are to be evaluated by CDC staff to determine if they should be taken to a hospital for medical evaluation and to get care as needed.⁴⁰ Asymptomatic persons are generally to be held under federal quarantine for up to 14 days if they have traveled from China’s Hubei province. However, asymptomatic persons who have traveled from other parts of China may be allowed to self-quarantine for 14 days.⁴¹

Personnel from DHS components—namely Customs and Border Protection (CBP) and the Transportation Security Administration (TSA)—are involved in excluding foreign nationals from entry and in assisting CDC personnel with implementation of quarantines for those who are permitted entry under these requirements.⁴²

⁴² *Ibid.*

Of note, in addition to announcing the United States' use of entry restrictions and quarantine authority on January 31, HHS Secretary Azar declared the 2019-nCoV outbreak to be a Public Health Emergency, pursuant to PHSA Section 319.⁴³ This declaration was not statutorily required for the abovementioned entry restrictions and quarantine requirements to go into effect. Each of these authorities is independent of the others.

Potential Effects of Travel Restrictions on the Spread of 2019-nCoV

Proposals to restrict the movement of people from affected regions or countries are part of early discussions when novel communicable diseases arise. WHO generally advises against nations imposing travel restrictions on other nations, citing limited evidence of the effectiveness of such measures in controlling outbreaks and the harmful economic effects they have on nations struggling with outbreaks.⁴⁴ Voluntary movement restrictions are urged instead (see text box below).

In sum, WHO recommends exit screening—screening for symptoms of illness at the point of departure—as preferable to entry screening (i.e., at the point of arrival) as a means to prevent spread of the disease. Other than interventions for individuals who are found to be ill at exit and/or entry screening, WHO does not recommend broader travel restrictions.

The effect of travel restrictions on the spread of communicable diseases is considered poorly understood for several reasons, including (1) limited contemporary examples for study; (2) the inherent variability in the natural progression of global disease outbreaks, even those caused by the same pathogen; (3) variation in actions taken by affected countries and restrictions imposed by other countries; and (4) difficulty in accounting for the effects of nongovernmental actions such as event cancellations and airline flight adjustments. In response to the emergence of 2019-nCoV, China imposed sweeping internal movement restrictions,⁴⁵ a measure that is likely, in later analyses, to obscure or confound any additional transmission-damping effects that the U.S. imposed travel restrictions may achieve.

Several studies have examined the potential effects of travel restrictions on disease spread, particularly looking at the global spread of influenza and at the SARS outbreak in 2002-2003. Of note, these analyses sometimes indicated delays in the speed of spread of an outbreak. However, the effect of travel restrictions on the ultimate geographic spread of the outbreak—or on the reduction of overall morbidity or mortality—is unclear, and the evidence base is limited. Some studies have found no effect of travel restrictions on overall morbidity and mortality of infectious disease.⁴⁶ Others have found that very strict travel restrictions may effectively prevent the spread of disease (i.e., complete border closure) or that travel restrictions might be more effective when combined with other infection control measures,

⁴³ HHS, “Secretary Azar Declares Public Health Emergency for United States for 2019 Novel Coronavirus,” press release, January 31, 2020.

⁴⁴ See, for example, World Health Organization (WHO), “No Rationale for Travel Restrictions,” May 1, 2009, in the context of the 2009 H1N1 influenza pandemic, https://www.who.int/csr/disease/swineflu/guidance/public_health/travel_advice/en/.

⁴⁵ Michael Levenson, “Scale of China’s Wuhan Shutdown Is Believed to Be Without Precedent,” *The New York Times*, January 22, 2020.

⁴⁶ Several such studies are discussed in Julia Belluz and Steven Hoffman, “The evidence on travel bans for diseases like coronavirus is clear: They don’t work,” *Vox*, January 23, 2020, <https://www.vox.com/2020/1/23/21078325/wuhanchina-coronavirus-travel-ban>.

such as quarantine and isolation.⁴⁷ In particular, compulsory movement restrictions may rely on public support in order to be effective, as well as to avoid discrimination and loss of public trust. Many suggest that if public support and trust are essential in any case, enlisting movement restriction through voluntary measures may be just as effective, with less societal disruption.⁴⁸

WHO Current Guidance Regarding International Travel During 2019-nCoV

“With the information currently available for the novel coronavirus, WHO advises that measures to limit the risk of exportation or importation of the disease should be implemented, without unnecessary restrictions of international traffic....

Advice for exit screening in countries or areas with ongoing transmission of the novel coronavirus 2019-nCoV (currently People’s Republic of China): Conduct exit screening at international airports and ports in the affected areas, with the [aim of] early detection of symptomatic travellers for further evaluation and treatment, and thus prevent exportation of the disease, while minimizing interference with international traffic;

Advice for entry screening in countries/areas without transmission of the novel coronavirus 2019-nCoV that choose to perform entry screening: The evidence from the past outbreaks shows that effectiveness of entry screening [to prevent disease spread] is uncertain.... Temperature screening to detect potential suspect cases at Point of Entry may miss travellers incubating the disease or travellers concealing fever during travel and may require substantial investments. A focused approach targeting direct flights from affected areas could be more effective and less resource demanding....Currently the northern hemisphere (and China) is in the midst of the winter season when Influenza and other respiratory infections are prevalent. When deciding implementation of entry screening, countries need to take into consideration that travellers with signs and symptoms suggestive of respiratory infection may result from respiratory diseases other than 2019-nCoV, and that their follow-up may impose an additional burden on the health system.... WHO advises against the application of any restrictions of international traffic based on the information currently available on this event.”

Source: WHO, “Updated WHO Advice for International Traffic in Relation to the Outbreak of the Novel Coronavirus 2019-nCoV,” January 27, 2020, https://www.who.int/ith/2019-nCoV_advice_for_international_traffic/en/.

In explaining the difference between the United States’ response to the 2019-nCoV and the 2009 h1n1 pandemic flu, CDC official Nancy Messonnier stated that in the case of 2019-nCoV, the virus was caught early, before it spread around the world, and that CDC is taking advantage of the window of opportunity to slow its spread into the United States.⁴⁹

Medical Countermeasures

Potential Products for Use in the 2019-nCoV Response

Medical countermeasures (MCMs) are medical products that may be used to treat, prevent, or diagnose conditions associated with emerging infectious diseases or chemical, biological, radiological, or nuclear (CBRN) threats. Examples of MCMs include biologics (e.g., vaccines, monoclonal antibodies), drugs (e.g., antimicrobials, antiretrovirals), and devices (e.g., diagnostic tests and personal protective equipment such as gloves,

respirators/masks, and gowns).⁵⁰ FDA regulates MCMs domestically. Currently, there are no FDA-approved MCMs for 2019-nCoV, although FDA has authorized the use of an *unapproved* diagnostic test via an Emergency Use Authorization (EUA).⁵¹ Federal agencies, pharmaceutical and biotech companies, nongovernmental organizations, and global regulators have been working to expedite the development and availability of MCMs for 2019-nCoV. Examples of such efforts include the following:

- **Diagnostics.** CDC developed the 2019-nCoV Real-Time RT-PCR Diagnostic Panel.⁵² On February 4, 2020, FDA issued an EUA, which permits the distribution of the unapproved diagnostic test to and for use by state and local partners.⁵³ (EUs are described in more detail below). Several federal agencies are working with industry partners to develop rapid diagnostic point-of-care tests for 2019-nCoV, including NIH, particularly through the National Institute of Allergy and Infectious Diseases (NIAID); ASPR, through the Biomedical Advanced Research and Development Authority (BARDA); and the Department of Defense (DOD).⁵⁴

On February 5, 2020, BARDA announced an Easy Broad Agency Announcement (EZ-BAA) to solicit applications for development funding of 2019-nCoV molecular diagnostics. The submissions must have a viable plan to meet requirements for the FDA to consider EUA within 12 weeks of an award.⁵⁵

- **Therapeutics.** Research and development into several treatment strategies for 2019-nCoV are underway by federal agencies, international partners, and industry. Drawing from research on the SARS and MERS coronaviruses, NIAID is assessing potential treatment strategies such as antiviral drugs and animal models that can be used to test potential MCMs. In addition, NIAID is developing assays and other research tools to study 2019-nCoV.⁵⁶ On February 4, 2020, BARDA announced that it would expand an existing collaboration with Regeneron Pharmaceuticals Inc. to

develop monoclonal antibodies that could be used to treat 2019-nCoV infections.⁵⁷ This partnership would build upon an existing technology used to develop monoclonal antibody therapeutics to treat Ebola and MERS.

Scientists in China are testing drugs currently approved for treatment of HIV, influenza (flu), or malaria for potential effectiveness against 2019-nCoV.⁵⁸ For example, in China, AbbVie's HIV drug Kaletra has been recommended as treatment for patients who have tested positive for 2019-nCoV, while the drug undergoes clinical testing. Johnson & Johnson has reportedly provided its HIV drug Prezcoibx to China to test as a potential treatment as well.⁵⁹ Scientists are also testing many experimental treatments in the research pipeline.⁶⁰ For example, Gilead is working with health authorities in China to determine whether its experimental antiviral drug Remdesivir can safely and effectively treat 2019-nCoV infections.⁶¹

- **Vaccines.** At least eight different 2019-nCoV vaccine development initiatives among federal agencies, industry, research institutions, and philanthropies have been announced.⁶² Of note, the NIAID Vaccine Research Center (VRC) is collaborating with the drug company Moderna and the Coalition for Epidemic Preparedness Innovations (CEPI) to advance a vaccine candidate. Moderna expects this vaccine to enter phase 1 clinical testing in the spring of 2020.⁶³ CEPI is also supporting vaccine development by the University of Queensland (Australia) and the drug companies GlaxoSmithKline and Inovio.⁶⁴ Johnson & Johnson stated that it is mobilizing efforts to develop a possible preventive vaccine candidate against 2019-nCoV.⁶⁵

FDA Emergency Use Authorization (EUA)

Clinical testing and the FDA review process typically take several years, so it will take time for MCMs in development to reach the commercial market. However, experimental products may become available in the United States prior to FDA approval pursuant to an EUA. FDA encourages industry and government sponsors (e.g., CDC) to engage with FDA prior to submitting a formal request for an EUA, if possible.

Under most circumstances, drugs, medical devices, and biologics may be introduced into interstate commerce only if they have been approved, cleared, or licensed by FDA. Under certain circumstances, however, FDA may permit a medical product to be provided to patients outside the standard regulatory framework, including through issuance of an EUA. In the absence of an approved MCM for 2019-nCoV, FDA may enable access to investigational MCMs by issuing an EUA, if the HHS Secretary declares that circumstances exist to justify the emergency use of an *unapproved product* or an *unapproved use of an approved medical product*.⁶⁶ The HHS Secretary's declaration must be based on one of four determinations; for example, a determination that there is an actual or significant potential for a public health emergency that affects or has significant potential to affect national security or the health and security of United States citizens living abroad.⁶⁷ Following the HHS Secretary's declaration, FDA, in consultation with ASPR, NIH, and CDC, may issue an EUA authorizing the emergency use of a specific drug, device, or biologic, provided that certain criteria are met (e.g., that there is no adequate, approved, and available alternative to the product).⁶⁸

On February 4, 2020, the HHS Secretary determined that there is a public health emergency that has a significant potential to affect national security or the health and security of United States citizens living abroad, and that involves the 2019-nCoV.⁶⁹ This determination allowed FDA to assess and ultimately allow the emergency use of the CDC-developed diagnostic test for 2019-nCoV. This emergency determination by the HHS Secretary is distinct from the Public Health Emergency declaration made pursuant to PHS Act Section 319.

⁶⁶ 21 U.S.C. §360bbb-3. For additional information, see CRS In Focus IF10745, *Emergency Use Authorization and FDA's Related Authorities*.

⁶⁷ 21 U.S.C. §360bbb-3(b)(1). A determination by the Secretary of Homeland Security that there is an actual or significant potential for a domestic emergency involving a heightened risk of attack with one or more CBRN agents; a determination by the Secretary of Defense that there is an actual or significant potential for a military emergency involving a heightened risk of attack with either with one or more CBRN agents, or with one or more agents that may cause or are associated with an imminently life-threatening and specific risk to United States military forces; a determination by the HHS Secretary that there is an actual or significant potential for a public health emergency that affects or has significant potential to affect national security or the health and security of United States citizens living abroad, and that involves one or more CBRN agents; or the identification by Secretary Homeland Security of a material threat pursuant to Public Health Service Act §319F-2.

⁶⁸ 21 U.S.C. §360bbb-3(c).

⁶⁹ This determination, made pursuant to Section 564(b)(1)(C) of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. §360bbb-3(b)(1)(C)), is noted on page 1 of the letter of authorization from FDA to CDC, advising of the authorization for emergency use of the CDC-developed diagnostic test. This letter is available at "Novel coronavirus (2019-nCoV) EUA Information" on the FDA webpage "Emergency Use Authorization," <https://www.fda.gov/emergencypreparedness-and-response/mcm-legal-regulatory-and-policy-framework/emergency-use-authorization>. See also footnote 53.

Health System Preparedness

There is concern that if 2019-nCoV spreads widely in the community, it will overwhelm existing health care system capacity to care for patients and prevent future infections. Given that it is currently flu season, many health care facilities are already at or near patient capacity. The ASPR is the principal advisor to the HHS Secretary on the public health and medical preparedness and response for public health emergencies.⁷⁰ While 2019-nCoV has not spread widely enough to warrant broad U.S. health system response activities, ASPR and CDC have indicated the following actions in preparation for the potential spread of 2019-nCoV:

- **Capacity assessment and monitoring.** ASPR and CDC are projecting the potential long-term impact of 2019-nCoV and assessing the capacity of the health care system to respond to a larger outbreak. A sustained response could engage the Regional Treatment Network for Ebola and Other Special Pathogens, a tiered health system response network developed with funding provided by Congress for response to the Ebola outbreak in 2015.⁷¹
- **Supply chain management.** Both ASPR and CDC have indicated that they are working with health care and industry partners to ensure an adequate supply of medical products needed to contain the outbreak, such as personal protective equipment (PPE; e.g., surgical masks). A chief concern in supply chain management is that many medical products or drugs are manufactured, at least in part, in China, the epicenter of the current outbreak.⁷²
- **Strategic National Stockpile (SNS).** The SNS, managed by ASPR, provides select medicines and medical supplies during public health emergencies when local supply chains are disrupted.⁷³ ASPR states it is working to ensure the adequacy of SNS supplies to prepare for the possible spread of 2019-nCoV.
- **Mobilization of health care surge capacity.** ASPR has indicated that it is working to ensure the availability of additional HHS health care support, such as deployment of the National Disaster Medical System (NDMS), in the event that local health care systems require augmentation to respond to the 2019-nCoV outbreak.⁷⁴

Response Funding

CDC and other federal agencies may have the authority needed to respond to the 2019-nCoV epidemic, but their ability to act may be affected by the availability of appropriations. Annual appropriations and standing transfer authority provide the HHS Secretary with some flexibility.⁷⁵ Upon a declaration of a Public Health Emergency pursuant to PHSA Section 319—which HHS Secretary Azar made on January 31, 2020—HHS may access a Public Health Emergency Fund,⁷⁶ but the fund does not have an available balance at this time. Separately, funding has generally not been available under the Robert T. Stafford Disaster Relief and Emergency Assistance Act (the Stafford Act) for the response to infectious disease outbreaks. As a result, Congress and the President provided supplemental appropriations for the response to the recent Ebola and Zika virus outbreaks in FY2015 and FY2016.⁷⁷

In 2018, Congress established an Infectious Diseases Rapid Response Reserve Fund (IDRRRF) for CDC, providing appropriations of \$50 million for FY2019 (P.L. 115-245) and \$85 million for FY2020 (P.L. 116-94), available until expended.⁷⁸ These funds may be made available for an infectious disease emergency if the HHS Secretary either (1) declares a Public Health Emergency pursuant PHSA Section 319, or (2) determines that the infectious disease outbreak has significant potential to occur and, if it occurs, the potential to affect national security or the health and security of U.S. citizens, both domestically and abroad.

Before HHS Secretary Azar declared the 2019-nCoV outbreak to be a Public Health Emergency under PHSA Section 319, he issued a determination on January 25, 2020, allowing the allotment of \$105 million from the IDRRRF for the 2019-nCoV response.⁷⁹ Secretary Azar had previously determined that the U.S. response to the Ebola outbreak in the Democratic Republic of Congo allowed the use of up to \$30 million from the IDRRRF. If both the Ebola and 2019-nCoV amounts are fully used, all funds currently in the IDRRRF would be exhausted.⁸⁰ On February 2, 2020, HHS reportedly notified Congress of its intention to use the Secretary's standing authority to transfer up to \$136 million for 2019-nCoV response efforts, of which \$75 million would be made available to CDC, \$52 million for ASPR, and \$8 million for the HHS Office of Global Affairs.⁸¹

⁷⁵ Annual appropriations acts give the HHS Secretary limited authority to transfer funds from one budget account to another within the department. For instance, a provision in the FY2020 HHS appropriations act (P.L. 116-94, Division A, Title II, §205) generally allows the Secretary to transfer up to 1% of the funds from any given account. However, in general, a recipient account may not be increased by more than 3%. Congressional appropriators must be notified in advance of any transfer. Another FY2020 appropriations provision (P.L. 116-94, Division A, Title V, §514) addresses the Secretary's authority to reprogram funds from one program, project, or activity in a given budget account to a different program, project, or activity within the same budget account. This provision places certain limits on such actions and clarifies the circumstances in which appropriations committees must be consulted in advance. (See P.L. 115-245).

⁷⁶ See HHS, "Legal Authority with Declaration of Public Health Emergency," <https://www.phe.gov/Preparedness/support/secauthority/Pages/default.aspx#phe>.

⁷⁸ The IDRRRF authority is codified at 42 U.S.C. §247d-4a.

⁷⁹ CQ Newsmaker Transcripts, "Health and Human Services Secretary Azar Holds News Conference on Coronavirus," January 28, 2020, <https://www.phe.gov/Preparedness/support/secauthority/Pages/default.aspx#phe>.

⁸⁰ Communication with CDC, January 28, 2020.

⁸¹ Yasmeen Abutaleb and Erica Werner, "HHS Notifies Congress that it May Tap Millions of Additional Dollars for Coronavirus Response," *Washington Post*, February 3, 2020. Likely the authority described in footnote 75.

CDC has an additional source of emergency support through the CDC Foundation, a 501(c)(3) public charity established by Congress “to support and carry out activities for the prevention and control of diseases, disorders, injuries, and disabilities, and for promotion of public health.”⁸² The CDC Foundation activated its Emergency Response Fund (ERF) to support 2019-nCoV response on January 27, 2020, as requested by CDC.⁸³ Funds have been donated to the ERF for this response by the Robert Wood Johnson Foundation, among others. Although the support provided by the foundation for outbreak response has been modest compared with supplemental appropriations, the foundation has greater spending flexibility and can sometimes procure response supplies and services more quickly than CDC through federal procurement processes.⁸⁴

The trajectory of the 2019-nCoV outbreak is uncertain. If the United States experiences sustained person-to-person transmission of the novel virus in the future, the nation’s public health and health care systems could be stretched to respond, and resources mobilized from the IDRRRF, HHS transfer authority, and the CDC Foundation may potentially be insufficient. Some Members of Congress have suggested that the Trump Administration consider a request for supplemental funding.⁸⁵

Chapter 473

ANOTHER CORONAVIRUS EMERGES: U.S. DOMESTIC RESPONSE TO 2019-nCoV*

Sarah A. Lister and Kavya Sekar

Archived Status

This Insight has been archived. Please refer to the new In Brief report on this topic:
CRS Report R46219, Overview of U.S. Domestic Response to the 2019 Novel Coronavirus (2019-nCoV)

THE EMERGENCE OF 2019-nCoV

On December 31, 2019, the World Health Organization (WHO) was informed of a cluster of pneumonia cases in Wuhan, China. Illnesses have since been linked to a previously unidentified strain of coronavirus, designated 2019 novel Coronavirus, or 2019-nCoV. To date, thousands have been infected, mostly in China, and over 100 have died. The disease has spread to several other countries, including the United States. As the scope of the epidemic widened in China, the U.S. Centers for Disease Control and Prevention (CDC) stated on January 27, 2020, that “the immediate health risk from the new virus to the general American public is low currently.” With the situation rapidly changing, both WHO and CDC post frequent updates.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11212, dated January 29, 2020.

Note: Surface projections on the viral envelope of a poultry coronavirus form the halo or “corona” that gives this virus group its name.

Figure 1. Coronaviruses, electron micrograph.

Coronaviruses (see *Figure 1*) are common respiratory pathogens, usually causing mild illnesses such as the common cold. The global health community is closely monitoring 2019-nCoV because of the severity of symptoms (including death) among those infected, and the speed of its spread worldwide. 2019-nCoV is causing the third-serious novel coronavirus outbreak in modern times, following severe acute respiratory syndrome (SARS) in 2002 and Middle East Respiratory Syndrome (MERS) in 2012. Experts do not know the origin of 2019-nCoV, though genetic analysis and other features suggest an animal source.

INFECTION AND TRANSMISSION

Health officials and researchers are still learning about 2019-nCoV. According to CDC, 2019-nCoV typically causes respiratory infections characterized by a fever, cough, and sometimes breathing difficulty—a suite of symptoms that is common during influenza season. Features that have yet to be clarified include routes of transmission (e.g., through the air, from contaminated surfaces), the incubation period (the time between infection and the

onset of symptoms), and whether an infected person without symptoms can transmit infection. Although it was first thought that all 2019-nCoV infections resulted from an animal contact, Chinese officials recently reported evidence of person-to-person transmission.

The U.S. Domestic Response

In the United States, communicable disease control involves collaboration among federal agencies, state health departments, and international partners. Authority to compel isolation (for sick patients), quarantine (for healthy exposed persons), and disease reporting generally rest in state law. The Secretary of Health and Human Services (HHS) and, by delegation, CDC have broad authority to assist in the control of communicable diseases through international cooperation, federal-state cooperation, and public health emergency response activities. In addition, CDC (by delegation) has explicit authority to detain, examine, and release persons arriving into the United States, and traveling between states, who are suspected of having a communicable disease.

Case Identification and Investigation

CDC has developed a diagnostic test for the 2019-nCoV virus, but it is not widely available. At this time, all testing is being done by CDC, which has announced plans to share the test with domestic and international public health partners. Until local testing is available, CDC urges clinicians to consider a patient's travel history and a 14-day incubation period in deciding whether to obtain patient specimens (e.g., blood, urine) for testing. Health care providers are urged to report possible cases to state and local health departments, which then report to CDC. CDC is facilitating the collection and transport of specimens.

Although CDC reports that no person-to-person transmission has been confirmed in the United States, disease investigation for confirmed cases involves *contact tracing*—identifying and evaluating individuals who had contact with the patient to determine if transmission has occurred. These investigations are generally conducted by state and local health officials.

Clinical Guidance

No vaccine or specific treatment exists for 2019-nCoV infection at this time. Based on knowledge of the novel virus and other coronaviruses, CDC has developed guidance for isolation and other precautions for *patients under investigation* or receiving supportive care for 2019-nCoV infection. A key goal is the prevention of disease transmission to health care workers, who may be exposed through high-risk procedures such as maintaining an ill patient on a ventilator.

Travel Notices and Entry Screening

CDC and the State Department have issued advisories to reconsider or avoid unnecessary travel to China, including a rare Level 4 advisory from the State Department to avoid all travel to Hubei Province. In collaboration with U.S. Customs and Border Protection, CDC is screening passengers returning on flights from certain areas of China at 20 U.S. airports, looking for symptoms of illness and disseminating information. On January 29, a U.S. government-chartered flight from Wuhan, China, repatriated 201 Americans, who have been

screened for illness and advised on procedures to follow should symptoms arise in the coming weeks.

Medical Countermeasures

CDC and the National Institutes of Health (NIH) continue to study the virus to inform response efforts. NIH reports that a vaccine candidate is in development and could be available for initial clinical trials within three months.

Considerations for Congress

CDC and other federal agencies may have the authority needed to respond to the 2019-nCoV epidemic, but they may lack available funds to support their efforts. Annual appropriations and standing transfer authority provide the HHS Secretary with some flexibility. Under certain circumstances the Secretary may access a Public Health Emergency Fund, but the fund does not have an available balance at this time.

Generally, funding has not been available under the Robert T. Stafford Disaster Relief and Emergency Assistance Act (the Stafford Act) for the response to infectious disease outbreaks. As a result, Congress provided supplemental appropriations for the response to the recent Ebola and Zika virus outbreaks.

Subsequently in 2018, Congress established an Infectious Disease Rapid Response Reserve Fund (IDRRRF) for CDC, providing \$50 million for FY2019 (P.L. 115-245) and \$85 million for FY2020 (P.L. 116-94), available until expended. These funds can be made available for an infectious disease emergency if the HHS Secretary either (1) declares a Public Health Emergency or (2) determines that the infectious disease outbreak has significant potential to occur and, if it occurs, the potential to affect national security or the health and security of U.S. citizens, both domestically and abroad. HHS Secretary Alex Azar has not declared the 2019-nCoV outbreak to be a Public Health Emergency, but has issued a determination allowing the allotment of \$105 million from the IDRRRF for the 2019-nCoV response.

The trajectory of the 2019-nCoV outbreak is unknown at this time. Congress may choose to conduct oversight of federal response efforts, and monitor the expenditure of funds, as the situation progresses.

Chapter 474

THE CORONAVIRUS: U.S.-CHINA ECONOMIC CONSIDERATIONS*

Karen M. Sutter and Michael D. Sutherland

The novel coronavirus outbreak (COVID-19) is slowing economic activity in China and raising concerns about potential U.S. supply chain vulnerabilities in a range of sectors that rely directly and indirectly on China-based suppliers. These sectors include medical supplies, pharmaceuticals, auto parts, microelectronics, and strategic raw materials. Similar to the outbreak of severe acute respiratory syndrome (SARS) in China in 2002-2003, most cases so far are concentrated in China, but the current number of infections is already an order greater and every Chinese province is affected. U.S. senior officials have expressed concerns about the completeness and timeliness of the information China is reporting, complicating assessments of the scope, trajectory, and economic impact of the outbreak. The Chinese government has also imposed tight content controls on media reporting and placed Sina Weibo, Tencent, ByteDance, and other Internet firms under “special supervision” of the Cyberspace Administration of China, further limiting coverage of the outbreak.

Economic Outlook

The coronavirus is hitting China during an economic downturn as the government grapples with U.S. tariffs and China’s counter tariffs, rising consumer inflation due in part to domestic pork shortages resulting from African swine fever, and efforts to rein in local government spending and shadow lending. China’s economic growth could go negative in the first quarter of 2020 and fall below 5% for the year, with more serious effects if the outbreak continues beyond March. In a sign the slowdown could last past March, the Chinese government cancelled several spring meetings: the State Council’s China Development Forum, the National People’s Congress annual legislative session, and the Canton Trade Fair.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IF11434, Updated March 2, 2020.

Source: New York Times, “Coronavirus Map: Tracking the Spread of the Outbreak,” March 2, 2020.

Figure 1. COVID-19 regional case map.

A key factor affecting the economic outlook in China is the ability of businesses to resume operations after the Lunar New Year was extended from late January until February 10, 2020. Business reopening has been uneven across sectors and locations in China. Many firms are awaiting government approvals to reopen and are facing difficulties in meeting new operating requirements, such as providing masks for employees. Foxconn, a Taiwan electronics firm that produces for Apple, has applied to reopen in early March. Resumption of transportation and travel appears to be a major obstacle. Chinese media has reported on employees struggling to return to work amid transportation shutdowns and contagion concerns. The American Chamber of Commerce in Shanghai reported on February 17, 2020, that most companies surveyed do not yet have sufficient staff to run a production line and face numerous logistics constraints. Almost half of the companies surveyed report that their global operations are already affected by the outbreak. These companies expect demand to be lower over the next several months.

The Chinese government has locked down cities in China’s provinces of Hubei (e.g., Wuhan, Ezhou) and Zhejiang (e.g., Wenzhou, Hangzhou, Ningbo, and Taizhou). In total, an estimated 90 cities across China face some form of restrictions. The Chinese government has leaned on online delivery services and the military for logistics support, and is restricting consumer activity across multiple cities.

Domestic and global transportation links have been significantly curtailed with ramifications for trade. Air services face reduced capacity with the canceling of passenger travel and restrictions on pilots and flight staff on cargo flights to third countries. Cargo operations in China depend on port staffing and are reportedly operating at significantly reduced capacity. While most businesses typically plan for a shut down during the Lunar New Year, including some stockpiling, companies are now likely to experience more serious shortages. Cargo shipments from China to the United States typically take approximately three weeks; slowdowns in maritime shipping could affect a wide range of industrial and consumer goods.

The Chinese government is trying to encourage economic activity, but restrictions on business reopening, travel, and transportation are hampering its support efforts. Unlike other

types of economic slowdowns, government stimulus cannot generate real economic activity on its own if business operations remain partially or completely shut down. The Chinese government is issuing economic support measures such as tax exemptions and special-purpose bonds. City governments in Beijing, Qingdao, Shanghai, and Suzhou are offering small- and medium- sized businesses in hard-hit industries support to reduce loans and delay payments for rent and social security. With a priority on social stability, localities are also offering preferences to companies that retain workers. In early February, China's central bank pumped \$57 billion into the banking system, capped banks' interest rates on loans for major firms, and extended deadlines for banks to curb shadow lending. The central bank has been setting the reference rate for China's currency stronger than its official close rate to keep it stable.

There have been press reports of shortages of medical supplies—N95 respirator masks, medical protective equipment, antiviral drugs—and food. In response, the government has repurposed some production facilities to meet health and medical needs, including the facilities of U.S. firms such as General Motors (GM) and 3M. In early February, the Commerce Ministry directed local governments to increase imports of medical supplies, production materials, and agricultural products, potentially providing U.S. export opportunities in these sectors.

Global Economic Impact

China's economy is globally connected through trade, investment, and tourism, and any slowdown and persistent travel and transportation restrictions beyond March are likely to pressure global supply chains and potentially create worldwide economic fallout. Measures to contain the outbreak have significantly curtailed domestic and global transportation links, preventing the transport of many products and manufacturing inputs. Passenger air traffic has slowed significantly, taking offline significant air cargo capacity for microelectronics and other products that ship by air. Production has slowed across China, with sharp slowdowns in sectors concentrated in Hubei, such as auto parts, LCD panels, and pharmaceuticals. Manufacturing that recently shifted offshore to other parts of Asia still often depends on intermediate inputs from China and thus is not insulated from China's production slowdown.

Disruptions in Chinese supply chains are expected to have a limited macroeconomic effect on developed markets in the short term but developing markets and Asia's developed economies, are more vulnerable. Vietnam, Taiwan, Malaysia, South Korea, Japan, Thailand, and Singapore all have strong supply chain links with China and are reporting supply shortages. South Korea's Hyundai and Kia, for example, announced production slowdowns in response to problems in securing auto parts from China. While developed economies might be insulated in the short term, the economic risks grow the longer the outbreak continues.

At the firm level, companies in sectors such as technology and autos or that are exposed to China's tourism, retail, or other services businesses could take a significant hit.

According to the United Nations World Tourism Organization, China's outbound tourism spending in 2018 was \$277 billion, of which an estimated \$36 billion was in the United States. U.S. business will likely be affected by China's slowdown, including through shortages of inputs, the cancellation of some commercial activity, and potential increased costs related to a strengthening U.S. dollar.

China’s Commerce Ministry is helping firms obtain free *force majeure* certifications—which allow firms to opt out of contractual obligations without legal recourse because of developments beyond their control—and China National Offshore Oil Company declared *force majeure* in cancelling some LNG imports.

BROADER CONSIDERATIONS FOR CONGRESS

Phase One Trade Deal: The crisis is calling into question China’s ability to implement the U.S.-China phase one trade deal signed in January 2020. Transportation constraints and a slowdown in demand could affect China’s import levels. The agreement has a *force majeure* provision that could give China flexibility in implementing its commitments. The deal was finalized in December 2019, when Chinese officials reportedly knew about the outbreak, which raises questions about the rationale and timing of the decision to include the *force majeure* provision. As part of the phase one trade deal, China and the United States on February 14, 2020, cut by 50% the tariffs they imposed in September 2019. China also announced a tariff exemption process for 700 tariff lines that include some agriculture, medical supplies, raw materials, and industrial inputs.

Pharmaceutical Market Access and IP: Pharmaceuticals are a component of *Made in China 2025* industrial plans that aim to create competitive advantages for China in certain strategic industries. The Chinese government restricts market access for foreign pharmaceutical firms, including the disclosure of proprietary information for drug trials and sales. The Wuhan Institute of Virology and China’s military recently applied to patent an adaption of an antiviral drug developed by California-based Gilead Sciences, Remdesivir. Also, Chinese firm BrightGene Bio- Medical Technology Co. announced it can produce a generic alternative to Remdesivir, potentially complicating Gilead’s way forward in China. Gilead’s patent application in China for Remdesivir use in coronaviruses has been pending since 2016. The Chinese government is also conducting an antitrust review of AbbVie’s acquisition of Allergan, Inc. and could set terms for the use or transfer of AbbVie’s antiviral intellectual property to benefit Chinese industry. China has required technology transfer in other antitrust reviews of foreign firms in *China 2025* sectors.

Table 1. Select U.S. Imports of healthcare products from China

Product	2019 value U.S.\$	2019 % of U.S. imports
Antibiotics	\$302,866,251	35%
PPE	\$1,852,214,083	30%
Medical Devices	\$3,911,308, 981	8.6%

Source: U.S. International Trade Commission, Assessed Customs Value.

Supply Chain Vulnerabilities: China’s role as a global supplier of medical personal protective equipment (PPE), medical devices, antibiotics, and active pharmaceutical ingredients means reduced production or exports from China could lead to shortages and increased costs of critical medical supplies in the United States. The outbreak is also likely to create shortages in China-sourced raw materials, manufacturing inputs, microelectronics, and finished goods.

Chapter 475

THE WUHAN CORONAVIRUS: ASSESSING THE OUTBREAK, THE RESPONSE, AND REGIONAL IMPLICATIONS*

Jennifer B. Nuzzo

Good afternoon, Chairman Bera, Ranking Member Yoho, and Members of the Committee. Thank you for giving me the chance to appear before you today to discuss the emergence and global spread of the 2019 novel coronavirus (2019 nCoV).

I am an Associate Professor in the Departments of Environmental Health and Engineering and Epidemiology at Johns Hopkins Bloomberg School of Public Health. I am also a Senior Scholar at the Johns Hopkins Center for Health Security. *The opinions expressed herein are my own and do not necessarily reflect the views of The Johns Hopkins University.* Our Center for Health Security's mission is to protect people's health from major epidemics and disasters and build resilience. We study the organizations, systems, and tools needed to prepare and respond. At the Center, I direct the Outbreak Observatory, which conducts operational research to improve outbreak response. My testimony is also influenced by my previous experiences as a public health practitioner. I have also served as a public health epidemiologist for New York City, where I conducted surveillance for infectious diseases.

My colleagues and I at the Johns Hopkins Center for Health Security have spent close to twenty years analyzing infectious disease outbreaks, including epidemics and pandemics, in attempt to better understand the resources, practices and policies that are need to prevent, mitigate and contain them. Like many others, we've been closely following novel coronavirus outbreak since it was first announced in China at the end of December. We've been trying to analyze and understand the risk the virus poses to the United States (US) and other countries around the world and to make recommendations to policy-makers, legislators and practitioners about what should be done to respond to this epidemic.

* This is an edited, reformatted and augmented version of United States House of Representatives Committee on Foreign Affairs Subcommittee on Asia, The Pacific, and Nonproliferation Publication, dated February 5, 2020.

I have two caveats regarding my testimony today. First, I have not been involved in the on-the-ground public health response to 2019 nCoV. My knowledge and assessment of this epidemic comes from my analysis of publicly shared information and conversations I have had with individuals and organizations that are closely involved in the response. Second, as you have likely heard, this is an evolving situation. Our knowledge of the virus is growing and changing as more data become available. What I offer you today is my best interpretation and judgment given the facts known at the time this testimony was prepared.

WHAT DO WE KNOW ABOUT 2019 nCoV?

The ongoing epidemic of 2019 nCoV was first recognized in the Wuhan city, Hubei Province, China. On December 31, 2019, health officials in Wuhan announced that they were investigating an outbreak of viral pneumonia involving 27 hospitalized cases in the city. Though the finding of viral pneumonia patients in any hospital during flu season is not by itself cause for alarm, health authorities were alerted to these cases by clinicians who noted the shared a common occupational exposure to the Huanan Seafood Wholesale Market. Wuhan health officials launched epidemiologic and environmental investigations. An official statement provided by the Wuhan Municipal Health Commission noted that all patients were treated in isolation and that there was no clear evidence of person-to-person transmission. Health officials closed the Huanan seafood market on January 1. One week later, health authorities in China announced that a novel coronavirus had been isolated from the viral pneumonia patients and the viral sequence was shared publicly.

Since the identification of 2019 nCoV as the likely cause of the viral pneumonia outbreak in Wuhan, we have learned several important things about the virus. First, the virus appears to be capable of sustained human-to-human transmission. Though it was initially thought that 2019 nCoV infection was limited to individuals with a history of exposure to the Huanan seafood market, cases have been found in individuals who reported never having visited markets in Wuhan. The appearance in other countries of multiple generations of 2019 nCoV cases who have not traveled to China provides additional evidence of sustained human to human transmission.

This finding differentiates the virus from the Middle East Respiratory Syndrome coronavirus (MERS-CoV), for which only limited human-to-human transmission has been reported.

Second, though severe illness and deaths have been reported, virus appears to be capable of causing a spectrum of disease. The emergence 2019 nCoV was first recognized among patients who were hospitalized with viral pneumonia. Since then 2019 nCoV cases with milder disease presentations have since been reported. Hospitalized patients also have a varied clinical picture—ranging from relatively mild symptoms to critical illness.

There is evidence that the virus jumped from animals and may have caused human infections earlier than initially recognized. A study published in the *Lancet* has shown some evidence the initial outbreak of 2019 nCoV may have started at the beginning of December or earlier--weeks before the outbreak was first recognized. It is not known when the virus became adapted to humans and capable to being spread via person-to person transmission.

Since the first report of human 2019 nCoV cases, more than 17,000 cases and 300 deaths (as of February 3, 2020) have been recorded in 23 countries. China accounts for the vast majority of cases. Cases have spread well beyond Wuhan—every province in China has since reported cases. From public reports and limited scientific studies published to-date, it appears as though the majority of reported deaths have occurred among elderly individuals and individuals with underlying medical conditions—patient groups known to be at risk for severe illness and death from other respiratory infections.

All deaths have occurred in China, with the exception of a death in the Philippines. The WHO has said that the deceased, who tested positive for nCoV, had also been infected with influenza and pneumococcus, a bacterium that causes pneumonia, bloodstream infections and meningitis. Outside of China, reported cases have so far been described as having mild disease presentations.

WHAT IS UNKNOWN?

Size and Scope of the Epidemic

What is not yet known is the true size and geographic scope of this epidemic. Though countries are quickly ramping up surveillance for this virus, it is likely that many lack the capacity to actively search for cases. Even countries that have mobilized surveillance programs are likely missing cases. Surveillance in China seem to be heavily focused on cases that show up at hospitals or clinics. Though this makes sense given limited testing capabilities, what it means is that individuals who don't seek medical attention for their infections are likely not being captured by existing surveillance in China. Outside of China, countries have, for the most part, only been testing people who have travelled to Wuhan or, in some cases, broader China.

Countries are not, as a matter of routine, looking for local cases that may resulted from infected individuals who entered the country before travel screening began.

Another complicating factor for surveillance is the occurrence of mild cases. Though there have been a concerning number of deaths and severe illnesses reported, the continued finding of mild cases raises the possibility that many more cases have occurred than have been detected. Mild cases are difficult to spot because their non-specific symptoms make them difficult to differentiate from other common respiratory illnesses. If individuals with mild symptoms don't seek medical attention, which is likely, and aren't tested, their infections will not be detected by most surveillance systems.

Hospitalization statistics are not reliable indicators of the burden of severe illness. China and other countries have been hospitalizing infected patients regardless of the severity of their symptoms. Infected patients are also remaining in hospitals until they are free of the virus, which may be well after patients' symptoms disappear.

Current US guidelines for testing for 2019 nCoV among individuals who are not contacts of confirmed cases are contingent on patients' symptoms and to travel to China. According to current guidelines from the US Centers for Disease Control and Prevention (CDC), individuals would likely not be tested for 2019 nCoV infection unless they are a symptomatic contact of a known case; traveled to Wuhan and experience fever and lower respiratory

illness; or, traveled to broader China and are hospitalized for a lower respiratory infection. It is not clear whether and how these testing criteria will change now that all provinces in China and more than 20 countries are reporting cases.

Severity

We don't yet have a clear understanding regarding the severity of illnesses caused by 2019 nCoV. The reasons for the observed discrepancies in severe illness and deaths inside and outside of China is not yet known. Though a concerning number of severe and critically ill patients and deaths have been reported, the frequency with which infected people get critically ill and die is not yet understood. But the apparent discrepancy in between the severity of symptoms and number of deaths among cases in China versus other countries raises the possibility that outbreaks in other countries may be less severe and/or comparable to other respiratory viruses, such as influenza.

The way most countries are conducting surveillance for nCoV will not allow us to directly estimate the percentage of infected individuals that develops severe illness and die. A key reason is that we are likely missing many cases, and, in particular mild cases. An outbreak caused by a new pathogen, like 2019 nCoV, is often not recognized until an unusual cluster of severely ill patients turn up in hospitals or an increase in deaths is noted and people launch an investigation to figure out why. As we stand up surveillance for novel viruses, such as 2019 nCoV, and begin to look for cases more broadly, we may identify milder cases in individuals who either didn't seek medical attention or whose symptoms were misdiagnosed. We may be vastly underestimating the total number of infected individuals, which means it is not accurate to estimate severity from the total number of reported cases and deaths. Nonetheless, people have been attempting to determine the severity by doing crude estimates with the limited information available. These crude estimates show that the percentage of deaths among total reported cases may be falling, which, if true, would be consistent with what we've observed in previous emerging infectious disease outbreaks.

Asymptomatic Spread

There have been a few case reports that have raised the possibility that individuals who experience no symptoms (asymptomatic) or have not yet developed symptoms (presymptomatic) may be capable of transmitting their infection to others. In addition, virus has been detected in patients after their symptoms went away, which raises the possibility of post-symptomatic spread. The extent to asymptomatic or presymptomatic cases are contributing to the larger epidemic is not known and the evidence supporting this is weak. If significant level of asymptomatic or presymptomatic transmission is occurring, this will make it harder to interrupt disease spread. However, the World Health Organization has said that asymptomatic patients are not likely to be the main driver of disease spread.

INTERNATIONAL RESPONSE

On January 30, the WHO declared the epidemic to be a Public Health Emergency of International Concern (PHEIC). This is the sixth time the WHO has designated an infectious disease event a PHEIC since the 2005 International Health Regulations (IHRs) gave the organization this power. This most recent declaration means that WHO is currently involved in the response to three simultaneous PHEICs— 2019 nCoV, Ebola in the Democratic Republic of Congo, and international spread of poliovirus.

In announcing that the global spread of 2019 nCoV constituted a PHEIC, the WHO Director General Tedros Ghebreyesus made clear that countries should respond with “facts, not fear.” The WHO has said that it does not recommend that countries implement travel or trade restrictions to prevent the importation of the virus. WHO has cautioned that countries that do take these measures could accelerate the spread of the virus by hindering the ability of responders and supplies to travel to where they are needed and by diverting public health resources from local disease control efforts. Nonetheless, many countries are implementing measures that the WHO has specifically advised against. Many countries, including the United States, have announced suspension of travelers from China, and an intention to quarantine travelers returning from China for up to 14 days. The IHRs were created to define the maximum measures countries could take to prevent the importation of disease; countries that take measures that are above what the WHO recommends do so in contravention of the IHRs.

But despite these unfortunate developments, I see in countries’ initial response to this nCoV epidemic some important signs for optimism. First, I must commend the astute clinicians in Wuhan, China who first recognized this unusual event. Front-line clinicians are our first defense against infectious disease outbreaks. That they recognized that their patients shared an unusual commonality—a link to the seafood market—is possibly the only reason why this outbreak was detected when it was and not later. This points to the importance of having well-trained clinicians who can recognize and rapidly report unusual events.

Second, I am greatly encouraged by the speed with which health authorities are expanding laboratory testing for a never-before-detected virus. This includes China, which isolated, identified and published the sequence of the novel coronavirus quickly, enabling other countries to develop their own laboratory tests. This also includes other countries, who immediately began screening and testing symptomatic travelers from China for a completely new virus. It is important to point out this rapid surveillance work reflects advanced laboratory capabilities that require investment, training and sustainment.

In addition, epidemiological investigations conducted in and shared by other countries have improved our understanding of the virus and its transmission. Thailand identified a 2019 nCoV case in a traveler from Wuhan who reported not having exposure to the initially implicated seafood market. This epidemiological finding first raised the possibility of infection among those without a connection to the Huanan market. The first evidence that this virus was capable of human-to-human transmission was provided by health officials in Vietnam, who identified and investigated a 2019 nCoV case in a 27-year old man who had not visited China, but had been caring for his sick father who had recently travelled from Wuhan.

Each of the above examples illustrates why it is so essential that countries have the public health capacities to prevent, detect and respond to infectious disease emergencies. The sharing of detailed surveillance and case reports from Vietnam, Thailand, and other countries that are now reporting cases is indispensable for global efforts to control the spread of this disease. It is also how, in the face of scientific uncertainties about the virus, WHO makes a determination of the global risk posed by the virus and how countries like the US gather the information they need to make decisions about how to protect their own citizens.

We should not take for granted the response successes that have occurred to date. The astute clinicians and the capacities to screen, diagnose and isolate patients with a novel virus and identify and monitor their contacts represent important global health security capacities—laboratory-based surveillance, trained epidemiologic workforce, infection prevention and control practices—that needed to be developed and maintained so that they could function in this epidemic. The speed with which countries have gathered and shared key epidemiological data has enabled others to better gauge risks posed by this virus and enhance response plans.

Comparing the 2019 nCoV epidemic to prior novel coronavirus outbreaks illustrates some of the progress that has been made in strengthening countries' global health security. In 2003, it took months before a novel coronavirus was identified as the cause of Severe Acute Respiratory Syndrome (SARS) as compared with weeks in the current epidemic. In 2015, the Republic of Korea experienced a large outbreak of Middle East Respiratory Syndrome coronavirus (MERS- CoV), in part due to delayed recognition and nosocomial spread of the virus. However, in 2019 Korea quickly detected and isolated an imported case with mild symptoms and became the third country outside of China to report cases. Korea and other countries that have experienced infectious disease challenges have done the hard work of improving their public health capacities deserve our recognition and gratitude.

The fact that countries are able to conduct surveillance for and epidemiological investigations of 2019 nCoV cases is the result of hard work and sustained investment, both by the countries themselves and by international donors. US technical and financial support has been critical to the development of surveillance systems and trained workforce in a number of countries now reporting 2019 nCoV cases. In the case of Thailand, US support spanned decades. Thailand now has a world class epidemiologic workforce and is a leader in global health security. In Vietnam, sustained US support and assistance have enabled the development an early warning surveillance system, which includes a network of emergency operations centers and enhancement of field epidemiology workforce training. These resources were used to support Vietnam's detection and response to Zika virus and are likely a supporting the country's on-going response to 2019 nCoV.

WORRISOME TRENDS IN GLOBAL READINESS FOR EPIDEMICS AND PANDEMICS

Much of the world is not fully prepared to respond to serious infectious disease epidemics or pandemics. Though there are positive examples of countries like Thailand and Vietnam rapidly responding to infectious disease threats, there are critical gaps in worldwide capacities that can inhibit the responses of many countries to this epidemic and others.

In October, my colleagues and I at the Johns Hopkins Center for Health Security and the Nuclear Threat Initiative, together with the research power of the Economist Intelligence Unit, released the Global Health Security Index (GHS Index), a first-ever assessment of 195 countries' global health security. The first GHS Index was the result of a sustained effort to define a framework to comprehensively and reproducibly understand and compare global health security at the national level and to collect and measure the extent to which countries' show evidence of having the capacities and capabilities required to respond to an epidemic or pandemic. The GHS Index builds on peer evaluations conducted by the WHO but covers all UN members, including China, and is regularly repeatable to measure progress. What we found is that no country, including the US, is fully prepared for significant infectious disease outbreaks. There is even less evidence that countries have demonstrated the ability to exercise these capacities or use them in an actual emergency. How unprepared is the globe as a whole? Out of a possible score of 100 points, we found that the average GHS Index score across 195 countries was just 40.2. Even countries with more resources are not ready, as the majority of high- and middle-income countries do not score above 50. What these results tell us is that action is urgently needed to improve countries' readiness for high-consequence infectious disease outbreaks.

In declaring the 2019 nCoV epidemic a PHEIC, WHO Director General Tedros Ghebreyesus said that a key reason for the declaration was a concern about the weakness of health systems in much of the globe. I share his worries. Among each of the 6 categories measured in our GHS Index, countries' scores were lowest (the average score was 26.4 out of 100) in the category that examined the readiness of national health systems to treat the sick and protect health workers.

This finding tracks with observed challenges in recent epidemics, such as the on-going epidemic of Ebola in Democratic Republic of Congo (DRC), which represents one of the three on-going PHEICs to which the WHO is currently responding. Though DRC has prior experience and success in containing Ebola outbreaks, disease transmission occurring in unprepared health facilities has played an important role in exacerbating the spread of disease. Transmission in healthcare facilities also occurred during the 2003 SARS epidemic and during outbreaks of MERS in 2015.

What this tells us is that there may be critical gaps in hospitals and other health facilities that will likely be the on the front-lines of responding to the 2019 nCoV epidemic. Many countries—including well-resourced ones like the US, may experience difficulties in responding to a surge of patients infected with 2019 nCoV. If the virus produces more severe illnesses than have been seen outside of China to-date, then the challenges of safely treating these patients will be even greater. The recent report of a healthcare worker in France who became infected with nCoV is a concerning development that speaks to the challenges that even well-resourced countries are likely to face in responding to this disease.

My worries about these identified weaknesses in national capacities to respond to epidemics and pandemics is increased by the lack of resources allocated to address them. The GHS Index showed that only 5% of countries—fewer than 10 countries overall—scored above 66.7 out of 100 points for financing health security. Prioritizing health security, especially in the strengthening of foundational health systems, will be critical in helping to control this epidemic, but also in addressing future infectious disease emergencies.

RECOMMENDATIONS TO IMPROVE US READINESS FOR CONTINUED SPREAD OF 2019 nCoV

The ultimate trajectory of the 2019 nCoV epidemic is hard to predict with certainty, but there are increasing signs that it may not be possible to contain the disease. We must plan for the possibility that 2019 nCoV will result in a global pandemic. My recommended priority actions to improve preparedness for global spread of 2019 nCoV are divided between international engagement and domestic readiness.

International engagement recommendations:

1. Halt the current US policy of denying visas to travelers from China and quarantining Americans returning from China.
2. Engage in a productive, collaborative dialogue with China to in order to ensure continued access to data and critical medical supplies

Domestic response recommendations:

1. Ensure health departments have the resources they need to conduct surveillance to promote proven mitigation measures, such as case isolation outside a hospital to the extent possible.
2. Ensure hospitals and other health facilities have the resources needed to safely treat a surge of patients.
3. Facilitate the development of medical countermeasures, such as diagnostics, vaccines, therapeutics.

The current US policy to deny visas to travelers from China and to quarantine returning Americans is not the right approach to controlling the spread of 2019 nCoV and may make us less safe. These measures are unlikely to keep the virus out of our country. The virus is spreading too quickly and too quietly for us to possibly know where all cases are. We do not have a complete picture of where in the world the virus is spreading to be able to stop infected people from coming to the US. It is also possible that unrecognized infections are occurring in US. In the weeks before the US began to screen travelers and airlines began reducing flights, thousands of people traveled to the US from China each day. And just because we are only looking for cases among people with a connection to China doesn't mean that those are the only individuals who are infected. As global case counts continue to grow and as more and more countries report cases, it will raise the question as to whether we should continue to focus on travel to Wuhan or broader China as criteria for testing. It is unlikely that we would be able to maintain our current approach to quarantine returning Americans and screen travelers if we needed to include additional countries or regions of the world.

I am deeply concerned that these measures will make us less safe by diverting public health resources from higher priority disease mitigation approaches that I describe below. It is not yet clear which agencies will have the responsibility of caring for and monitoring returning travelers who have been placed into quarantine. It is possible that local health authorities would play a lead role, as they did in monitoring travelers returning from West Africa during the Ebola epidemic of 2014, which required considerable resources that had to

be diverted from other public health activities. Caring for and monitoring even small numbers of quarantined individuals would likely be a challenge for many health departments and would require a large investment of resources.

By singling out China for travel bans, we are, effectively penalizing it for openly reporting and sharing data about the epidemic. Our ability to respond to epidemics depends on having access to epidemiological information generated by other countries. Geographically-targeted measures may exacerbate the social and economic tolls of this epidemic and send a signal to countries that it may not be in their best interests to be forthcoming about disease outbreaks. This could diminish countries' willingness to be transparent about outbreaks and allow diseases to spread before outbreaks are uncovered, which would make everyone less safe. We should reward countries that report cases through offers of help and assistance.

It is in our best interest to maintain a productive and collaborative relationship with China and to help it better respond to the spread of 2019 nCoV disease. To appropriately gauge how the US should respond to this evolving health threat, it will be critical to continue to have access to data from China. Just prior to the US's announcement of travel bans, China indicated that it would allow US scientists in to participate in the epidemic response. This was an important development and may have led to an improved understanding of the current epidemic. But it is now questionable whether this offer is still viable, given the on-going travel restrictions.

It is essential that we maintain positive relationships with China to ensure the continued availability of essential goods. China is a major producer of the medical resources which the US will need to respond to this epidemic, such as surgical masks and other personal protective equipment. Our dependence on medical supplies from China is not just restricted to products needed for responding to this epidemic. For example, China is a major global producer of raw materials for commonly-used medicines, such as the blood thinner heparin. The US recently experienced shortages in its supplies of heparin, which is derived from pigs, due to China's efforts to cull pigs in order to control the spread of African Swine Fever. What this example should indicate to us that should help China respond to 2019 nCoV to ensure that the actions it takes do not interrupt the production and distribution of essential goods. There are already reports suggesting that China's massive efforts to restrict the movements of tens of millions of individuals may interrupt the production of goods. China needs our help and it is in our best interest to provide it.

We must now contemplate the possibility of pandemic spread of 2019 nCoV and must plan for how we will mitigate the impacts of the virus. In my view, it is highly likely that the United States will continue to see cases of 2019 nCoV, despite the recently implemented travel bans and quarantines. Though there are still important unknowns, this epidemic bears a number of similarities to the 2009 influenza A/H1N1 pandemic. It is essential that we plan for the possibility that the 2019 nCoV virus will follow a similar pattern to the 2009 pandemic. If the virus continues to circulate and cases keep climbing, the probability of community-wide transmission will increase. Responding to a novel virus for which no specific therapy or vaccine yet exists leaves only the possibility of mitigating the disease spread. What measures we take to find cases and mitigate disease spread will be determined by the observed severity and the availability of resources. If there continue to be concerns about the severity of the virus, our priority should be to rapidly detect and isolate of cases and identify and monitor their close contacts for signs of illness. Communities will likely consider other mitigation

strategies, such as limiting public gatherings and closing schools, but the operational feasibility of these measures must be examined, and potential adverse consequences (e.g., reduced availability of healthcare personnel due to childcare obligations) should be considered. If the disease continues to demonstrate mild tendencies in cases outside of China, we may consider focusing efforts on protecting those most likely to become ill and preventing deaths.

We must ensure that responding agencies have the resources necessary to respond to 2019 nCoV cases across the country. Each of the above scenarios requires that health departments and hospitals have the resources they need to conduct surveillance to promote proven mitigation measures, such as case isolation. Unless patients require medical attention, they should be isolated outside of a hospital to reduce the possibility that they infect healthcare workers and other patients. Hospitals and other health facilities will need resources to safely treat a surge of patients.

If the number of 2019 nCoV cases in the US continues to grow, the US Congress will likely be called to appropriate emergency funds to enable states to respond to the virus. During the 2009 pandemic, the Ebola epidemic of 2014, and the response to the Zika pandemic, the US Congress approved emergency supplemental funding that went to support state and local response efforts. The current fiscal outlook in states is such that they will be unable to fully respond without additional federal funding. Federal agencies such as HHS and CDC, which have been responding to multiple on-going disease emergencies, such as Ebola in DRC, have already indicated that they may need additional emergency response funds to support the 2019 nCoV response.

Government leadership is needed to facilitate the development of medical countermeasures, including diagnostics. Though a number of efforts to develop a vaccine have been announced, it is likely that a usable vaccine will not be available for some time. Research is also being conducted to develop therapeutic medicines, which may help those with severe illness and prevent deaths. Enhanced diagnostic tools are essential to the use of both vaccine and therapeutics, yet comparatively less attention has been given to the need to accelerate the development of new diagnostic tools. CDC is currently conducting all of the testing for 2019 nCoV in the US, but has plans to roll out testing capabilities to state public health labs. This will be important to reduce current lag times in getting test results for persons under investigation for 2019 nCoV and to meet a likely increase in the demand for testing as case counts rise. However, there is also a need for diagnostics in clinical settings. If more patients seek care at healthcare facilities, there will be an increased need for diagnostic tools to help clinicians rule out infection with nCoV, make decisions about cohorting or isolating patients, and to determine course of therapy.

CONCLUSION

The points I have raised today hopefully paint a picture of an epidemic that is in many ways complex and evolving, but for which we are increasingly gaining clarity. International collaboration will be essential for continuing to monitor and learn about the virus and the epidemic it is causing. Even amid uncertainty, we should root our response in evidence. Without evidence to guide our actions, we may inadvertently exacerbate the toll of this

epidemic. In evaluating how we should respond to this public health emergency, we must consider not only whether the measures will work, but also whether the ends justify the means. While we want to do the utmost to protect health, we don't want to pursue measures that will extract a greater toll on societies and our economy than the virus would alone. We must continually assess whether our response strategies are matched to the level of threat that the virus poses and adapt our approach as new information becomes available. With evidence mounting of continued global spread despite aggressive actions being taken by countries, it is becoming clear that a change of course may be needed. Instead of trying to implement measures that likely will not work to prevent the virus from entering our country, we should focus on efforts that we know will help to lessen its impacts, such as ensuring that federal, state and local health agencies, and hospitals and health clinics have the resources they need to diagnose, isolate and safely treat cases, and to promote feasible approaches to community mitigation that are most likely to mitigate disease spread. For this we will need government leadership and additional investments.

Chapter 476

WHAT YOU NEED TO KNOW ABOUT CORONAVIRUS DISEASE 2019 (COVID-19)*

Department of Health and Human Services

WHAT IS CORONAVIRUS DISEASE 2019 (COVID-19)?

Coronavirus disease 2019 (COVID-19) is a respiratory illness that can spread from person to person. The virus that causes COVID-19 is a novel coronavirus that was first identified during an investigation into an outbreak in Wuhan, China.

CAN PEOPLE IN THE U.S. GET COVID-19?

COVID-19 is spreading from person to person in China, and limited spread among close contacts has been detected in some countries outside China, including the United States. At this time, however, this virus is NOT currently spreading in communities in the United States. Right now, the greatest risk of infection is for people in China or people who have traveled to China. Risk of infection is dependent on exposure. Close contacts of people who are infected are at greater risk of exposure, for example health care workers and close contacts of people who are infected with the virus that causes COVID-19. CDC continues to closely monitor the situation.

HAVE THERE BEEN CASES OF COVID-19 IN THE U.S.?

Yes. The first case of COVID-19 in the United States was reported on January 21, 2020. The current count of cases of COVID-19 in the United States is available on CDC's webpage at <https://www.cdc.gov/coronavirus/2019-ncov/cases-in-us.html>.

* This is an edited, reformatted and augmented version of Department of Health and Human Services Publication, No. CS 314937-A 02, dated February 21, 2020.

HOW DOES COVID-19 SPREAD?

The virus that causes COVID-19 probably emerged from an animal source, but now it seems to be spreading from person to person. It's important to note that person-to-person spread can happen on a continuum. Some diseases are highly contagious (like measles), while other diseases are less so. At this time, it's unclear how easily or sustainably the virus that causes COVID-19 is spreading between people. Learn what is known about the spread of newly emerged coronaviruses at <https://www.cdc.gov/coronavirus/2019-ncov/about/transmission.html>.

WHAT ARE THE SYMPTOMS OF COVID-19?

Patients with COVID-19 have had mild to severe respiratory illness with symptoms of

- fever
- cough
- shortness of breath

WHAT ARE SEVERE COMPLICATIONS FROM THIS VIRUS?

Many patients have pneumonia in both lungs.

HOW CAN I HELP PROTECT MYSELF?

The best way to prevent infection is to avoid being exposed to the virus that causes COVID-19.

THERE ARE SIMPLE EVERYDAY PREVENTIVE ACTIONS TO HELP PREVENT THE SPREAD OF RESPIRATORY VIRUSES. THESE INCLUDE

- Avoid close contact with people who are sick.
- Avoid touching your eyes, nose, and mouth with unwashed hands.
- Wash your hands often with soap and water for at least 20 seconds. Use an alcohol-based hand sanitizer that contains at least 60% alcohol if soap and water are not available.

IF YOU ARE SICK, TO KEEP FROM SPREADING RESPIRATORY ILLNESS TO OTHERS, YOU SHOULD

- Stay home when you are sick.
- Cover your cough or sneeze with a tissue, then throw the tissue in the trash.
- Clean and disinfect frequently touched objects and surfaces.

WHAT SHOULD I DO IF I RECENTLY TRAVELED TO CHINA AND GOT SICK?

If you were in China within the past 14 days and feel sick with fever, cough, or difficulty breathing, you should seek medical care. Call the office of your health care provider before you go, and tell them about your travel and your symptoms. They will give you instructions on how to get care without exposing other people to your illness. While sick, avoid contact with people, don't go out and delay any travel to reduce the possibility of spreading illness to others.

IS THERE A VACCINE?

There is currently no vaccine to protect against COVID-19. The best way to prevent infection is to avoid being exposed to the virus that causes COVID-19.

IS THERE A TREATMENT?

There is no specific antiviral treatment for COVID-19. People with COVID-19 can seek medical care to help relieve symptoms.

For more information: www.cdc.gov/COVID19.

Chapter 477

CORONAVIRUS DISEASE 2019 (COVID-19) SITUATION SUMMARY*

Centers for Disease Control and Prevention

This is an emerging, rapidly evolving situation and CDC will provide updated information as it becomes available, in addition to updated guidance.

BACKGROUND

CDC is responding to an outbreak of respiratory disease caused by a novel (new) coronavirus that was first detected in China and which has now been detected in almost 70 locations internationally, including in the United States. The virus has been named “SARS-CoV-2” and the disease it causes has been named “coronavirus disease 2019” (abbreviated “COVID-19”).

On January 30, 2020, the International Health Regulations Emergency Committee of the World Health Organization declared the outbreak a “public health emergency of international concernexternal icon” (PHEIC). On January 31, 2020, Health and Human Services Secretary Alex M. Azar II declared a public health emergency (PHE) for the United States to aid the nation’s healthcare community in responding to COVID-19.

SOURCE AND SPREAD OF THE VIRUS

Coronaviruses are a large family of viruses that are common in people and many different species of animals, including camels, cattle, cats, and bats. Rarely, animal coronaviruses can infect people and then spread between people such as with MERS-CoV, SARS-CoV, and now with this new virus (named SARS-CoV-2).

* This is an edited, reformatted and augmented version of Centers for Disease Control and Prevention Publication, Updated March 3, 2020.

The SARS-CoV-2 virus is a betacoronavirus, like MERS-CoV and SARS-CoV. All three of these viruses have their origins in bats. The sequences from U.S. patients are similar to the one that China initially posted, suggesting a likely single, recent emergence of this virus from an animal reservoir.

Early on, many of the patients at the epicenter of the outbreak in Wuhan, Hubei Province, China had some link to a large seafood and live animal market, suggesting animal-to-person spread. Later, a growing number of patients reportedly did not have exposure to animal markets, indicating person-to-person spread. Person-to-person spread was subsequently reported outside Hubei and in countries outside China, including in the United States. Some international destinations now have apparent community spread with the virus that causes COVID-19, including in some parts of the United States. Community spread means some people have been infected and it is not known how or where they became exposed. Learn what is known about the spread of this newly emerged coronaviruses.

Confirmed COVID-19 Cases Global Map.

[View larger image and see a list of locations.](#)

COVID-19 CASES IN THE U.S.

Situation in U.S.

- Imported cases of COVID-19 in travelers have been detected in the U.S.
- Person-to-person spread of COVID-19 was first reported among close contacts of returned travelers from Wuhan.
- During the week of February 23, CDC reported community spread of the virus that causes COVID-19 in California (in two places), Oregon and Washington. Community spread in Washington resulted in the first death in the United States from

COVID-19, as well as the first reported case of COVID-19 in a health care worker, and the first potential outbreak in a long-term care facility.

Illness Severity

Both MERS-CoV and SARS-CoV have been known to cause severe illness in people. The complete clinical picture with regard to COVID-19 is not fully understood. Reported illnesses have ranged from mild to severe, including illness resulting in death. While information so far suggests that most COVID-19 illness is mild, a report external icon out of China suggests serious illness occurs in 16% of cases. Older people and people with certain underlying health conditions like heart disease, lung disease and diabetes, for example, seem to be at greater risk of serious illness.

Learn more about the symptoms associated with COVID-19.

There are ongoing investigations to learn more. This is a rapidly evolving situation and information will be updated as it becomes available.

RISK ASSESSMENT

Outbreaks of novel virus infections among people are always of public health concern. The risk from these outbreaks depends on characteristics of the virus, including how well it spreads between people, the severity of resulting illness, and the medical or other measures available to control the impact of the virus (for example, vaccine or treatment medications). The fact that this disease has caused illness, including illness resulting in death, and sustained person-to-person spread is concerning. These factors meet two of the criteria of a pandemic. As community spread is detected in more and more countries, the world moves closer toward meeting the third criteria, worldwide spread of the new virus.

Reported community spread of COVID-19 in parts of the United States raises the level of concern about the immediate threat for COVID-19 for those communities. The potential public health threat posed by COVID-19 is very high, to the United States and globally.

At this time, however, most people in the United States will have little immediate risk of exposure to this virus. This virus is NOT currently spreading widely in the United States. However, it is important to note that current global circumstances suggest it is likely that this virus will cause a pandemic. This is a rapidly evolving situation and the risk assessment will be updated as needed.

Current risk assessment:

- For most of the American public, who are unlikely to be exposed to this virus at this time, the immediate health risk from COVID-19 is considered low.
- People in communities where ongoing community spread with the virus that causes COVID-19 has been reported are at elevated, though still relatively low risk of exposure.
- Healthcare workers caring for patients with COVID-19 are at elevated risk of exposure.

- Close contacts of persons with COVID-19 also are at elevated risk of exposure.
- Travelers returning from affected international locations where community spread is occurring also are at elevated risk of exposure.

CDC has developed guidance to help in the risk assessment and management of people with potential exposures to COVID-19.

WHAT MAY HAPPEN

More cases of COVID-19 are likely to be identified in the coming days, including more cases in the United States. It's also likely that person-to-person spread will continue to occur, including in communities in the United States. It's likely that at some point, widespread transmission of COVID-19 in the United States will occur.

Widespread transmission of COVID-19 would translate into large numbers of people needing medical care at the same time. Schools, childcare centers, workplaces, and other places for mass gatherings may experience more absenteeism. Public health and healthcare systems may become overloaded, with elevated rates of hospitalizations and deaths. Other critical infrastructure, such as law enforcement, emergency medical services, and transportation industry may also be affected. Health care providers and hospitals may be overwhelmed. At this time, there is no vaccine to protect against COVID-19 and no medications approved to treat it. Nonpharmaceutical interventions would be the most important response strategy.

CDC RESPONSE

Global efforts at this time are focused concurrently on containing the spread and mitigating the impact of this virus. The federal government is working closely with state, local, tribal, and territorial partners, as well as public health partners, to respond to this public health threat. The public health response is multi-layered, with the goal of detecting and minimizing introductions of this virus in the United States. CDC is operationalizing all of its pandemic preparedness and response plans, working on multiple fronts to meet these goals, including specific measures to prepare communities to respond to local transmission of the virus that causes COVID-19. There is an abundance of pandemic guidance developed in anticipation of an influenza pandemic that is being repurposed and adapted for a COVID-19 pandemic.

HIGHLIGHTS OF CDC'S RESPONSE

- CDC established a COVID-19 Incident Management System on January 7, 2020. On January 21, CDC activated its Emergency Operations Center to better provide ongoing support to the COVID-19 response.

- The U.S. government has taken unprecedented steps with respect to *travel* in response to the growing public health threat posed by this new coronavirus:
 - Effective February 2, at 5pm, the U.S. government suspended entry of foreign nationals who have been in China within the past 14 days.
 - U.S. citizens, residents, and their immediate family members who have been in Hubei province and other parts of mainland China are allowed to enter the United States, but they are subject to health monitoring and possible quarantine for up to 14 days.
 - On February 29, the U.S. government announced it was suspending entry of foreign nationals who have been in Iran within the past 14 days.
 - CDC has issued the following travel guidance related to COVID-19:
 - China — Level 3, Avoid Nonessential Travel — updated February 22;
 - Hong Kong — Level 1, Practice Usual Precautions — issued February 19;
 - Iran — Level 3, Avoid Nonessential Travel — updated February 28;
 - Italy — Level 3, Avoid Nonessential Travel — updated February 28;
 - Japan — Level 2, Practice Enhanced Precautions — updated February 22;
 - South Korea — Level 3, Avoid Nonessential Travel — updated February 24.
 - CDC also recommends that all travelers reconsider cruise ship voyages into or within Asia at this time.
- CDC is issuing clinical guidance, including:
 - On January 30, CDC published guidance for healthcare professionals on the clinical care of COVID-19 patients.
 - On February 3, CDC posted guidance for assessing the potential risk for various exposures to COVID-19 and managing those people appropriately.
 - On February 27, CDC updated its criteria to guide evaluation of persons under investigation for COVID-19.
 - On February 28, CDC issued a Health Alert Network (HAN): Update and Interim Guidance on Outbreak of COVID-19.
- CDC has deployed multidisciplinary teams to support state health departments case identification, contact tracing, clinical management, and communications.
- CDC has worked with the Department of State, supporting the safe return of Americans who have been stranded as a result of the ongoing outbreaks of COVID-19 and related travel restrictions. CDC has worked to assess the health of passengers as they return to the United States and provided continued daily monitoring of people who are quarantined.

This is a picture of CDC's laboratory test kit for severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). CDC is shipping the test kits to laboratories CDC has designated as qualified, including U.S. state and local public health laboratories, Department of Defense (DOD) laboratories and select international laboratories. The test kits are bolstering global laboratory capacity for detecting SARS-CoV-2.

Resize iconView Larger.

- An important part of CDC's role during a public health emergency is to develop a test for the pathogen and equip state and local public health labs with testing capacity.
 - After distribution of a CDC rRT-PCR test to diagnose COVID-19 to state and local public health labs started, performance issues were identified related to a problem in the manufacturing of one of the reagents. Laboratories were not able to verify the test performance.
 - CDC worked on two potential resolutions to this problem.
 - CDC developed a new protocol that uses two of the three components of the original CDC test kit to detect the virus that causes COVID-19 after establishing that the third component, which was the problem with the original test, can be excluded from testing without affecting accuracy. CDC is working with FDA to amend the existing Emergency Use Authorization (EUA) for the test, but in the meantime, FDA granted discretionary authority for the use of the original test kits.
 - Public health laboratories can use the original CDC test kit to test for the virus that causes COVID-19 using the new protocol.
 - Further, newly manufactured kits have been provided to the International Reagent Resource [external icon](#) for distribution.
 - Combined with other reagents that CDC has procured, there are enough testing kits to test more than 75,000 people.
 - In addition, CDC has two laboratories conducting testing for the virus that causes COVID-19. CDC can test approximately 350 specimens per day.
 - Commercial labs are working to develop their own tests that hopefully will be available soon. This will allow a greater number of tests to happen close to where potential cases are.
 - CDC has grown the COVID-19 virus in cell culture, which is necessary for further studies, including for additional genetic characterization. The cell-grown virus was sent to NIH's BEI Resources Repository [external icon](#) [external icon](#) for use by the broad scientific community.

CDC RECOMMENDS

- Everyone can do their part to help us respond to this emerging public health threat:
 - It's currently flu and respiratory disease season and CDC recommends getting a flu vaccine, taking everyday preventive actions to help stop the spread of germs, and taking flu antivirals if prescribed.
 - If you are a healthcare provider, be on the look-out for:
 - People who recently traveled from China or another affected area and who have symptoms associated with COVID-19, and
 - People who have been in close contact with someone with COVID-19 or pneumonia of unknown cause. (Consult the most recent definition for patients under investigation [PUIs].)
 - If you are a healthcare provider or a public health responder caring for a COVID-19 patient, please take care of yourself and follow recommended infection control procedures.
 - If you are a close contact of someone with COVID-19 and develop symptoms of COVID-19, call your healthcare provider and tell them about your symptoms and your exposure.
- If you are a resident in a community where person-to-person spread of COVID-19 has been detected and you develop COVID-19 symptoms, call your healthcare provider and tell them about your symptoms.
- For people who are ill with COVID-19, but are not sick enough to be hospitalized, please follow CDC guidance on how to reduce the risk of spreading your illness to others. People who are mildly ill with COVID-19 are able to isolate at home during their illness.
- If you have been in China or another affected area or have been exposed to someone sick with COVID-19 in the last 14 days, you will face some limitations on your movement and activity for up to 14 days. Please follow instructions during this time. Your cooperation is integral to the ongoing public health response to try to slow spread of this virus.

Chapter 478

SCIENCE AND TECH SPOTLIGHT: CORONAVIRUSES*

Timothy M. Persons

WHY THIS MATTERS

Coronaviruses can spread rapidly and cause outbreaks with high mortality rates. They were not considered a major risk for humans until the SARS outbreak in 2002. Since then, there have been multiple highly contagious outbreaks originating in animals and spreading to humans—most recently the outbreak in Wuhan, China of Coronavirus Disease 2019 (COVID-19).

THE SCIENCE

What is it? While the outbreak of COVID-19 in China has brought the term coronavirus into daily usage, coronaviruses can vary in severity. They can cause respiratory issues, such as pneumonia, and are believed to be one cause of the common cold. According to the Centers for Disease Control and Prevention (CDC), most people will be infected by a coronavirus at some point in their lifetimes. As of March 2020, seven coronaviruses have been identified that can cause illness in humans. Most infections result in mild to moderate symptoms, such as runny nose, headache, cough, sore throat, fever, and a run-down feeling.

Coronaviruses are most commonly transmitted by coughing, sneezing, person-to-person contact, and touching objects that have viral particles on them, according to CDC. The best prevention is washing hands with soap and avoiding contact with people who are sick or work in quarantine areas. Current treatment methods are limited, and research is being fast-tracked to develop a vaccine against existing and emerging coronaviruses.

Recent high-profile coronavirus outbreaks have raised new concern because of high mortality rates relative to the coronaviruses that cause the common cold. In addition, the

* This is an edited, reformatted and augmented version of the United States Government Accountability Office Publication, No. GAO-20-472SP Coronaviruses, dated March 2020.

severe coronaviruses can cause both upper- and lower-respiratory-tract infections, including pneumonia.

Since 2002, there have been three severe outbreaks of respiratory illness caused by coronaviruses, all three originating in animals. In 2002, an outbreak of Severe Acute Respiratory Syndrome (SARS) began in China and had a mortality rate of approximately 10 percent. In 2012, an outbreak of Middle East Respiratory Syndrome (MERS) had a mortality rate reported as high as 34 percent. Most recently, a December 2019 outbreak of a new coronavirus, SARS-CoV-2—which causes COVID-19—has seen a high infection rate, with over 70,000 infected and over 2,600 deaths—a mortality rate of approximately 3 percent as of February 24th, 2020, according to the World Health Organization (WHO). Estimates of the reproductive ratio, or R_0 , for COVID-19 have also indicated that it has the potential to spread rapidly. These estimates are tentative, however, because the R_0 is a complex epidemiologic measure that is context-specific and affected by numerous biological, behavioral, and environmental factors.

How does it work? Coronaviruses are believed to work in similar ways. Viral particles attach themselves to specific molecules, known as receptors, on the surface of a human or animal cell, allowing the virus to enter. Once inside, the virus discards its outer coating, releasing its genetic material into the host cell. This can occur in many cells at the same time. The virus can then use the cell's own mechanisms—for example, the mechanism to produce proteins based on genetic code—to replicate itself. The hijacking of the cell's functions causes the release of new viral particles and restarting the process, either in more cells of the same host or in another host that becomes infected.

Coronaviruses mutate rapidly compared to other viruses, enabling them to adapt to new environments. Coronaviruses are ribonucleic acid (RNA) viruses, which are more prone to random mutations than deoxyribonucleic acid (DNA) viruses. Because DNA viruses, like chickenpox and many others, are more stable, it is easier to create long term effective vaccines against them. In contrast, RNA viruses, like flu, may regularly require new vaccines.

Sources (left to right): National institute of Allergy and Infectious Diseases; Centers for Disease Control and Prevention, Alissa Eckert, Dan Higgins. | GAO-20-472SP.

Figure 1. Electron microscope image and schematic of coronavirus particles (Middle East Respiratory Syndrome Coronavirus and general coronavirus respectively).

Source: GAO analysis of Fenner's Veterinary Virology edited by N. James MacLachlan and Edward J. Dubovi. | GAO-20-472SP.

Figure 2. Schematic of how a coronavirus infects host cells. This process is similar for all RNA viruses, the large class to which coronaviruses belong.

Generally, coronaviruses originate in animals, with the most likely origin being bats, and can spread from animal to animal. In environments where humans and multiple animal species mix, such as live animal markets and farms, there is an increased likelihood that a coronavirus can mutate and spread into humans. The original animal vector for SARS-CoV-2 has not yet been determined.

How mature is it? Several procedures, including diagnostic testing, are available to address coronaviruses, and are being used in the U.S. response. However, vaccines and therapies are not yet mature.

In the wake of the COVID-19 outbreak, Chinese researchers isolated the virus, sequenced its genome, and shared the results with the scientific community. The sequencing allowed CDC to develop a diagnostic test that is now being distributed to local labs. Also, based on genetic similarities, a vaccine developed for SARS has been recommended by researchers as a possible option for SARS-CoV-2. And researchers are drawing on the SARS-CoV-2 genome to help determine which aspects of the coronavirus might be used to develop a more specific vaccine against it.

For those already infected, doctors are trying a drug originally made to treat Ebola that also works against SARS and MERS. The first U.S. patient diagnosed with COVID-19 was treated with this drug under compassionate use (a policy allowing some use of non-approved drugs), and additional antivirals are being tested.

Source: World Health Organization (WHO). | GAO-20-472SP.

Figure 3. The recent outbreaks of coronavirus-caused diseases known to infect humans (COVID-19 numbers are confirmed and as reported by China).

OPPORTUNITIES

- Identification of common targets in coronaviruses to develop
- vaccines against all coronaviruses.
- Increased coordination by industry, academia, and government could improve awareness of treatment options for future outbreaks.
- Advances in predictive infectious disease modelling to better inform decisions about interventions in future outbreaks.

Challenges

- For rapid deployment, potential treatments need to be prepared prior to an outbreak despite limited information and incentives.
- Development of vaccines for RNA viruses requires frequent evaluation and reformulation. It is complex, costly, and time consuming.
- Outbreak detection requires constant monitoring and coordination among nations, which can be impeded by more closed societies.
- Global economic consequences of such outbreaks can be serious. According to multiple economic forecasting models, SARS cost the global economy \$30-100 billion.

Policy Context and Questions

- To what extent are surveillance and clinical data, computational models, and information sharing mechanisms in place to promote agile and effective risk management during disease outbreaks?
- What policies and mechanisms are in place or needed to help maintain medical supply chains during global disease outbreaks?

Selected GAO Work

- National Biodefense Strategy: Additional Efforts Would Enhance Likelihood of Effective Implementation GAO-20-273
- Infectious Disease Threats: Funding and Performance of Key Preparedness and Capacity-Building Programs GAO-18-362

Chapter 479

COVID-19: CURRENT TRAVEL RESTRICTIONS AND QUARANTINE MEASURES*

Edward C. Liu

The United States, along with many countries, is responding to an outbreak of a respiratory disease, now referred to as COVID-19, which is caused by a novel coronavirus first detected in mainland China's Hubei Province in late 2019. Cases of COVID-19 have now been detected in several countries, including the United States.

To date, the federal government has taken two key actions to deter persons with suspected COVID-19 infection from entering the country or spreading the virus to persons within the United States. First, the federal government has restricted many non-U.S. nationals (aliens) who recently travelled to mainland China or Iran from entering the United States. Second, the federal government has imposed a quarantine requirement on all persons entering the United States, regardless of citizenship status, who have recently been to mainland China. This Legal Sidebar examines the legal authorities underlying these actions, as well as possible legal challenges to their use.

ENTRY RESTRICTIONS

To deter the entry of aliens into the United States who may have been exposed to COVID-19, President Trump has invoked his authority over alien entry under Section 212(f) of the Immigration and Nationality Act (INA). That provision allows the President to "suspend the entry of all aliens, or any class of aliens" whose entry he "finds . . . would be detrimental to the interests of the United States." Under this authority, President Trump issued a Proclamation on January 31, 2020, generally suspending the entry of any foreign national who had been in mainland China at some point within the prior 14 days. But lawful permanent residents (LPRs), most immediate relatives of U.S. citizens and LPRs, and some other groups, such as some airplane and ship crew members, are exempted from this

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. LSB10415, dated March 5, 2020.

restriction, as are those with prior presence in Hong Kong or Macau. On February 29, 2020, President Trump issued a second Proclamation that similarly suspends the entry of any foreign national who has been in Iran within the prior 14 days, in addition to making minor amendments to the earlier Proclamation.

While this appears to be the first time Section 212(f) has been used to control the spread of a communicable disease, the provision has been previously invoked to restrict foreign travelers from coming into the United States. Perhaps most notably, Section 212(f) provided the legal basis for the Trump Administration's imposition of the so-called "travel ban" on certain foreign nationals from designated countries. In the context of a challenge to that invocation of Section 212(f), the Supreme Court held that the provision "exudes deference to the President in every clause" and gives him mostly unfettered discretion to decide "when to suspend entry," "whose entry to suspend," "for how long," and "on what conditions." In light of the deference afforded to the President's determinations over these matters, coupled with the amount of evidence demonstrating the communicability of COVID-19, it seems unlikely that a court would find that the Proclamations issued with respect to mainland China and Iran exceed the scope of the President's authority under Section 212(f).

QUARANTINE AND ISOLATION

The Administration's January 31, 2020, Proclamation also directed the Secretary of Homeland Security "to regulate the travel of persons and aircraft to the United States to facilitate the orderly medical screening and, where appropriate, quarantine of persons who enter the United States and who may have been exposed to the virus." To this end, on February 2, 2020, the U.S. Department of Homeland Security (DHS) imposed screening and quarantine rules for persons – including U.S. nationals, LPRs, and their immediate family members – who arrive in the United States within 14 days after having been in mainland China. Those persons travelling by air must arrive at one of 11 designated airports where they will be screened. On March 2, 2020, DHS imposed similar requirements for air travelers who were recently present in Iran. Screened persons will be taken to a medical facility for isolation and treatment if fever, cough, or difficulty breathing is detected. Asymptomatic persons are generally to be held under federal quarantine for 14 days from the time they left mainland China if they visited Hubei Province. But asymptomatic persons whose recent travel did not include Hubei Province are asked to self-quarantine for 14 days. State and local health authorities are to provide oversight of individuals who self-quarantine.

Authority for these quarantine rules comes from Section 361 of the Public Health Service Act, which authorizes the U.S. Department of Health and Human Services (HHS) to promulgate and enforce regulations "necessary to prevent the introduction, transmission, or spread of communicable diseases from foreign countries into the States or possessions, or from one State or possession into any other State or possession." Besides authorizing the apprehension and examination of "any individual reasonably believed to be infected with a communicable disease in a qualifying stage" who is "moving or about to move from a State to another State," Section 361 also authorizes the apprehension and quarantine of persons who are not engaged in interstate travel, but are reasonably believed "to be a probable source of infection to individuals who, while infected with such disease in a qualifying stage, will be

moving from a State to another State.” To facilitate these quarantine requirements, HHS promulgated an interim final rule, effective February 7, 2020, requiring airlines with flights arriving in the United States to transmit to HHS’s Centers for Disease Control and Prevention (CDC) identifying information about passengers or crew who may be at risk of exposure to communicable disease.

In addition to federal quarantine authority, states may quarantine or isolate persons as public health risks using their police powers. State mandatory quarantine laws vary, with some implemented through public health orders issued by state health departments, and others effectuated through court orders authorizing the detention of an individual upon some evidentiary showing that the person poses a public health risk.

Possible Constitutional Challenges

Because quarantine requirements involve a deprivation of a person’s liberty to move freely, they have occasionally been challenged on constitutional grounds. Specifically, the Supreme Court “repeatedly has recognized that civil commitment for any purpose constitutes a significant deprivation of liberty that requires due process protection.” Accordingly, quarantine measures may be challenged as violating the Constitution’s *substantive* or *procedural* due process protections.

Substantive due process challenges center on whether a governmental action “is so egregious, so outrageous, that it may fairly be said to shock the contemporary conscience,” without regard to “the fairness of the procedures used to implement” the action. Recent challenges to quarantine and isolation for public health reasons have borrowed from substantive due process precedents involving involuntary commitment. In that context, substantive due process challenges question whether the government has set forth an adequate justification to support the deprivation of liberty effected by a quarantine policy (a type of challenge that might also be viewed through an equal protection rather than a due process lens). In either case, a substantive due process challenge to quarantine policies affecting those suspected of COVID-19 seems unlikely to succeed given the degree of public health risk posed by the virus. Courts have recognized that expeditious actions by government officials are frequently required to protect public health or safety, and have been reluctant to find substantive due process violations even if those actions are found to be erroneous after the fact.

There might also be concerns as to whether a quarantine policy satisfies the Constitution’s *procedural due process* requirements. These requirements concern whether the *process* attending a particular deprivation by the government – in this case the restraint on liberty during the quarantine period – is fair. The degree of protection required by procedural due process is a “flexible” concept, requiring an examination of the private interests at stake; the risk of an erroneous deprivation of such interest and the probable value of additional safeguards; and the government’s interests. In the context of state action, the Supreme Court has said that the Due Process Clause typically “requires some kind of a hearing *before* the State deprives a person of liberty,” but has also held that the “necessity of quick action by the State or the impracticality of providing any predeprivation process” may mean that a *post-deprivation* remedy is constitutionally adequate. Here, the government may argue that the

contagiousness of the COVID-19 virus may make predeprivation process impractical before requiring the quarantine of a person suspected of COVID-19 infection.

In 2014, a federal district court applying this standard in the context of a Friday-to-Monday quarantine of a nurse who had recently been in contact with Ebola patients found that the lack of a predeprivation hearing was not a clear violation of due process because quarantine is “necessarily prophylactic and peremptory.” However, the court noted that the relatively short duration of the quarantine (80 hours) also factored into its conclusion. Moreover, to the extent that post-deprivation procedural due process claims may be made, government actors may still enjoy qualified immunity to civil liability if the action “does not violate clearly established statutory or constitutional rights of which a reasonable person would have known.”

OTHER LEGAL ISSUES

Federal officials have warned that as the United States begins to see “community spread” of COVID-19, actions taken to limit entry of persons into the country may be less important than domestic quarantine and isolation of persons already present in the United States. Shifts in the types of actions taken in response to the disease may also present distinct legal issues from those discussed above. For example, questions have arisen regarding the employment protections that workers may have under federal laws, such as the Family and Medical Leave Act (or perhaps under state laws), if those workers fall ill, are placed under mandatory quarantine, or choose to stay home voluntarily to avoid exposure to themselves or others or to take care of an infected family member.

The federal government may also seek to facilitate the distribution of medical countermeasures to COVID-19 as they continue to develop through the issuance of emergency use authorizations (EUA) under Section 564 of the Federal Food, Drug, and Cosmetic Act. One such EUA was issued on February 4, 2020, to enable emergency use of the CDC’s real-time COVID-19 diagnostic test. On February 29, 2020, FDA issued additional guidance stating that it would not object to the use of certain diagnostic tests prior to issuance of an EUA. In addition, the federal government has the authority to waive liability for manufacturers, distributors, and providers of such countermeasures, under the Public Readiness and Emergency Preparedness Act, which it most recently invoked with respect to Ebola countermeasures.

Chapter 480

COVID-19: FEDERAL ECONOMIC DEVELOPMENT TOOLS AND POTENTIAL RESPONSES*

Michael H. Cecire

The current coronavirus disease (COVID-19) outbreak has led to tens of thousands of cases and thousands of deaths worldwide. In addition to the disease's mortality and public health effects, it may have potentially significant economic implications, including productivity losses, supply chain disruptions, labor dislocation, and potential financial pressure on businesses and households. Relatively few federal programs are available to provide timely economic relief to affected businesses. This Insight considers the outbreak's economic development implications and policy considerations for Members of Congress who have shown interest in addressing the economic dimensions of this public health issue.

COVID-19 ECONOMIC DEVELOPMENT IMPLICATIONS

COVID-19 is a newly designated disease caused by a previously undetected coronavirus. Most cases have been reported in China, with additional cases on every inhabited continent. Clusters of illness have occurred in South Korea, Japan, Singapore, Italy, and Iran. For more information on the health and epidemiological aspects of COVID-19, see CRS products R46219 and IF11421.

The COVID-19 outbreak is foremost a public health issue. However, the epidemic itself and containment measures in China and elsewhere could have significant economic implications for the United States and globally. In the short-term, the COVID-19 outbreak is primarily a threat to businesses dependent on supply chains in China, or for exports there. However, many economists have warned that a more prolonged crisis may see broader economic disruptions if workplaces and schools are closed to contain the outbreak, and medical and food supplies dwindle due to disrupted supply and increased demand.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11228, dated February 28, 2020.

In China, mass containment measures have disrupted global supply chains and capital markets. In the near term, the outbreak's effects on the U.S. economy could be limited to localized disruptions for businesses and workers—particularly in communities dependent on technology manufacturing and tourism. In certain cases, supply chain issues may stall production, prevent companies from fulfilling orders, and potentially impact firm revenues.

In a prolonged or wider epidemic, supply chain issues may further compound. Growth could slow further, and affected companies may be forced to furlough or lay off workers, and others may slow hiring. As demonstrated in China and elsewhere, social distancing measures can effectively stop local economic activity, which may impact localized labor markets, household finances, and governmental tax revenues and service delivery. Additional considerations include potential shortages of medical supplies and foodstuffs, other ancillary health effects, and the U.S. medical and public health system's ability to cope with a significant outbreak.

CONSIDERATIONS FOR CONGRESS

Many Members of Congress have heard concerns from constituents affected by supply chain-, exports-, and tourism-related disruptions from the outbreak. Relatively few federal programs exist to provide timely relief to businesses for outbreak-related disruptions. Some programs include

- The Small Business Administration (SBA) administers disaster and non-disaster loans for small businesses and organizations, and supports an extensive network of SBA-affiliated resource partners who provide management and technical assistance to small businesses;
- The Department of the Treasury's Community Development Financial Institution Fund supports organizations that provide loans to businesses, homebuyers, community developers, and investors in distressed areas; and
- The Department of Agriculture's (USDA) Rural Development program offers limited services to support rural businesses to create or retain jobs.

In the event that disruptions continue and grow, public and non-profit organizations may consider tapping various federal economic development resources, including

- The Department of Housing and Urban Development's Community Development Block Grant (CDBG) program may be used for technical assistance, community assets, and workforce development;
- The Department of Commerce's Economic Development Administration programs may be used to diversify local economic bases;
- USDA programs can provide technical assistance and infrastructure support; and
- Federal regional commissions and authorities support economic diversification, workforce development, and technical assistance in their service areas.

Federal economic development programs are generally not equipped to provide rapid support to firms or communities affected by public health emergencies, though unemployment compensation programs have the ability to rapidly respond and provide immediate income support. In response to a COVID-19 outbreak, Congress may consider measures used in past disasters or economic crises:

- CDBG authorities for disaster recovery (CDBG-DR) could be utilized to address the outbreak's economic impact. Previous CDBG-DR uses included loans and grants to small and medium-sized enterprises (SMEs), workforce development, and community stabilization.
- Public health-related disruption eligibility for SBA's Economic Injury Disaster Loans (EIDLs) could be made explicit. EIDLs provide up to \$2 million to small businesses that suffer economic injury following disasters such as hurricanes. EIDLs may be awarded if the President issues a disaster or emergency declaration, or a disaster declaration by the SBA administrator upon request from a state governor.
- In response to the 2007-2009 recession, federal measures included direct interventions to stabilize industries and markets. A similar effort could support affected industries or supply chains, and/or federal loan guarantees to assist affected SMEs.
- In the recession, Unemployment Compensation benefits were temporarily augmented and extended, with some costs temporarily assumed by the federal government. Disaster Unemployment Assistance, which provides federally funded unemployment benefits to those unable to work as a result of a federally declared disaster and otherwise ineligible for regular benefits, could be a model for responding to public health emergencies.
- Following a federally declared disaster, the Internal Revenue Service (IRS) can provide tax relief to affected individuals. The IRS could provide such allowances to affected individuals and SMEs affected by a public health emergency.

Other federal emergency authorities could be utilized in more severe scenarios for individual and public assistance. In such cases, localities with major revenue shortfalls from federally declared disasters—such as those highly dependent on a dislocated industry, such as tourism—could utilize Community Disaster Loans, which provide up to \$5 million in liquidity and are potentially forgivable. The President may also call upon the Defense Production Act (DPA) to mobilize key segments of the economy in response to the outbreak. In major national emergencies, DPA authorities may be used to rebalance disrupted critical supply chains, and to allocate and procure emergency supplies.

Chapter 481

COVID-2019: GLOBAL IMPLICATIONS AND RESPONSES*

***Tiaji Salaam-Blyther, Susan V. Lawrence,
Sara M. Tharakan and Frank Gottron***

OVERVIEW

As of February 27, 2020, the novel coronavirus first identified in patients in Wuhan, China, in early January 2020 had spread to over 45 countries, including the United States. Daily new cases reported outside China now exceed those reported in China. The World Health Organization (WHO) has declared the outbreak a Public Health Emergency of International Concern but has resisted labeling it a “pandemic.” WHO Director-General Tedros Adhanom Ghebreyesus stated on February 26 that using the word “pandemic” could “signal that we can no longer contain the virus, which is not true.” WHO has named the new virus “severe acute respiratory syndrome coronavirus 2” (SARS-CoV-2) and the disease that it causes “coronavirus disease 2019” (COVID-19).

THE VIRUS

Coronaviruses are a large family of zoonotic viruses (viruses transmissible between animals and humans) that can cause illness ranging from the common cold to more severe diseases such as Middle-East Respiratory Syndrome (MERS) and Severe Acute Respiratory Syndrome (SARS). The most common symptoms among confirmed COVID-19 patients include fever, dry cough, and shortness of breath. As of February 26, 2020, WHO reported more than 80,000 confirmed COVID-19 cases globally, including more than 2,700 deaths. All but 5% of the cases and 60 of the deaths were in mainland China, and over 80% of cases in

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IF11421, Updated February 27, 2020.

mainland China were reported in Hubei Province, whose capital is Wuhan. Of confirmed COVID-19 patients in China, about 80% experienced only mild symptoms, 13% experienced severe symptoms, and 6% became critically ill. Outside mainland China, the jurisdictions with the highest reported caseloads were South Korea, Italy, Japan, and Iran. More than 700 cases have been detected from the Diamond Princess cruise ship, docked alongside Yokohama, Japan. In addition to China, the United States and Germany have confirmed community transmission of COVID-19, indicating the global response may need to move from a containment strategy to one of mitigation.

Within days of Chinese scientists' sequencing the virus, scientists around the globe developed lab tests to diagnose COVID-19. Current diagnostic supplies are insufficient to meet global demand, however. While trying to increase supply of these tests, developers are also trying to create faster, cheaper, and more easily administered tests. No specific treatments or vaccines for COVID-19 exist. The U.S. National Institutes of Health (NIH) indicated in late January that a candidate vaccine for COVID-19 could be ready for early-stage human testing within three months, compared to the 20 months it took to begin early-state development of an investigational SARS vaccine.

Source: World Health Organization and National Health Commission of the People's Republic of China.

Figure 1. Locations with confirmed COVID-19 cases globally, as of February 27, 2020.

DEVELOPMENTS IN CHINA

China first reported cases of pneumonia of an unknown cause to the WHO on December 31, 2019. Chinese scientists isolated the virus on January 7, 2020, and shared its genetic sequence with the world on January 12. China's government did not raise the alarm to its own people until January 20, however. Before then, the government appears to have worked to suppress information about the outbreak. Observers have suggested that by withholding

information, the government may have squandered an early window of opportunity to stem the virus's spread.

After January 20, Chinese authorities began taking aggressive actions to prevent the virus from spreading further. By February 20, they had imposed *cordon sanitaires*, or restrictions on movement in and out of defined areas, on as many as 760 million people. Human rights groups and others have questioned such measures. Bruce Aylward, the Canadian co-team leader of a WHO- China Joint Mission on COVID-19, praised China, however, for a "bold approach" that "changed the course" of the epidemic and prevented "probably hundreds of thousands of cases of COVID-19 in China."

The WHO-China Joint Mission, which included representatives from the U.S. Centers for Disease Control and Prevention (CDC) and NIH, carried out an on-the- ground investigation of the outbreak in China from February 16 to 24. The mission concluded that the epidemic in China peaked and plateaued between January 23 and February 2, and has been waning since. Aylward acknowledged that the outbreak is not yet controlled in Wuhan, and he warned of the risk that the epidemic could "come back up again as people start to move again, the shops start to open, restaurants open, schools open." He said that risk was "being managed very carefully."

WHO RESPONSE

PHEIC. Following the emergence of a disease that might be deemed a Public Health Emergency of International Concern (PHEIC), WHO convenes an advisory group, the IHR Emergency Committee, to review data and make recommendations to the WHO Director-General. At its second meeting, on January 30, WHO's 15-member IHR Emergency Committee for Pneumonia due to the Novel Coronavirus COVID-19 concluded the outbreak had become a PHEIC. That day, WHO Director-General Tedros issued a PHEIC declaration, prompting countries to take specific actions, including heightening surveillance and reporting of the disease. In the case of the United States, Department of Health and Human Services (HHS) Secretary Alex Azar declared "a public health emergency for the entire United States." A PHEIC declaration can prompt countries to provide additional resources for global and domestic response and enable WHO to access certain emergency funding, such as from the United Nations Central Emergency Response Fund (CERF) and the World Bank Pandemic Emergency Financing Facility (PEF).

Pandemic Designation Debate. Some observers have questioned why WHO has not labeled the global COVID- 19 outbreak a pandemic. On February 26, WHO Director-General Tedros defended WHO's caution, arguing, "For the moment, we are not witnessing sustained and intensive community transmission of this virus, and we are not witnessing large-scale severe disease or death." He nonetheless urged countries to "prepare for a potential pandemic," stating, "Every country needs to be ready to detect cases early, to isolate patients, trace contacts, provide quality clinical care, prevent hospital outbreaks, and prevent community transmission."

WHO Funds. On February 5, WHO announced a \$675 million COVID-19 preparedness plan for February through April. It aims to provide international coordination and operational support, bolster country readiness and response capacity (particularly in low-resource

countries), and accelerate relevant research and innovation. As of February 26, six donors had pledged to provide \$30.0 million in support of the plan and WHO had received \$1.4 million.

U.S. RESPONSE

Leadership. On January 29, President Donald J. Trump announced the formation of the President's Coronavirus Task Force, led by HHS and coordinated by the National Security Council. On February 27, the President appointed Vice President Mike Pence as the Administration's COVID-19 task force leader, and the Vice President subsequently appointed President's Emergency Plan for AIDS Relief (PEPFAR) Ambassador Deborah Birx as the "White House Coronavirus Response Coordinator."

Funds for Global COVID-19 Control. On February 7, the Department of State and the U.S. Agency for International Development committed to use up to \$100 million of existing funds to assist China and other affected countries with COVID-19 responses. HHS has made available up to \$105 million from the Infectious Disease Rapid Response Reserve Fund for domestic and international COVID-19 responses. In late February, the Administration stated those funds would be exhausted by the end of the month. On February 24, the Administration asked Congress for an emergency supplemental appropriation of \$1.25 billion for COVID-19 response efforts. The Administration also asked Congress to allow repurposing of another \$1.25 billion in existing funds from across the government, including HHS funds for current Ebola response activities.

Travel Issues and Evacuations. On January 31, 2020, the President suspended the entry into the United States of any foreign national who has been in China within the prior 14 days. On February 2, the Department of Homeland Security issued instructions subjecting returning U.S. citizens with recent travel to Hubei Province to mandatory quarantine of up to 14 days. The State Department has issued a Level 4 ("Do Not Travel") advisory for China and evacuated U.S. citizens and others from Wuhan. The Department ordered the mandatory departure of nonemergency U.S. personnel and their families from the U.S. consulate in Wuhan, and the voluntary departure of nonemergency U.S. personnel and their families from other diplomatic posts in China. The U.S. government also repatriated U.S. citizens from the *Diamond Princess* cruise ship in Japan.

Chapter 482

CORONAVIRUS DISEASE 2019 (COVID-19) HOSPITAL PREPAREDNESS ASSESSMENT TOOL*

Department of Health and Human Services

All U.S. hospitals should be prepared for the possible arrival of patients with Coronavirus Disease 2019 (COVID-19). All hospitals should ensure their staff are trained, equipped and capable of practices needed to:

- Prevent the spread of respiratory diseases including COVID-19 within the facility
- Promptly identify and isolate patients with possible COVID-19 and inform the correct facility staff and public health authorities
- Care for a limited number of patients with confirmed or suspected COVID-19 as part of routine operations
- Potentially care for a larger number of patients in the context of an escalating outbreak
- Monitor and manage any healthcare personnel that might be exposed to COVID-19
- Communicate effectively within the facility and plan for appropriate external communication related to COVID-19

The following checklist does not describe mandatory requirements or standards; rather, it highlights important areas for hospitals to review in preparation for potential arrivals of COVID-19 patients.

* This is an edited, reformatted and augmented version of Department of Health and Human Services Publication.

Elements to be assessed

1. Infection prevention and control policies and training for healthcare personnel (HCP):

- Facility leadership including the Chief Medical Officer, quality officers, hospital epidemiologist, and heads of services (e.g., infection control, emergency department, environmental services, pediatrics, critical care) has reviewed the Centers for Disease Control and Prevention's COVID-19 guidance. <https://www.cdc.gov/coronavirus/2019-nCoV/guidance-hcp.html>. ☐
- Facility provides education and job-specific training to HCP regarding COVID-19 including: ☐
 - Signs and symptoms of infection
 - How to safely collect a specimen
 - Correct infection control practices and personal protective equipment (PPE) use
 - Triage procedures including patient placement
 - HCP sick leave policies and recommended actions for unprotected exposures (e.g., not using recommended PPE, an unrecognized infectious patient contact)
 - How and to whom COVID-19 cases should be reported

2. Process for rapidly identifying and isolating patients with confirmed or suspected COVID-19:

- Signs are posted at entrances with instructions to individuals with symptoms of respiratory infection to immediately put on a mask and keep it on during their assessment, cover their mouth/nose when coughing or sneezing, use and dispose of tissues, and perform hand hygiene after contact with respiratory secretions. ☐
- Facemasks are provided to coughing patients and other symptomatic individuals upon entry to the facility. ☐
- Signs are posted in triage areas (e.g., ED entrances) advising patients with fever or symptoms of respiratory infection and recent travel outside the US, specifically to China, to immediately notify triage personnel so appropriate precautions can be put in place. ☐
- Alcohol based hand sanitizer for hand hygiene is available at each entrance and in all common areas. ☐
- Facility provides tissues and no-touch receptacles for disposal of tissues in waiting rooms and in common areas. ☐
- Facility has a separate well-ventilated space that allows waiting patients to be separated by 6 or more feet, with easy access to respiratory hygiene and cough etiquette supplies. ☐
- Facility has a process to ensure patients with confirmed or suspected COVID-19 are rapidly moved to an Airborne Infection Isolation Room (AIIR). ☐
- Alternatively, for patients that cannot be immediately placed in a room for further evaluation, a system is provided that allows them to wait in a personal vehicle or outside the facility (if medically appropriate) and be notified by phone or other remote methods when it is their turn to be evaluated. ☐
- Triage personnel are trained on appropriate processes (e.g., questions to ask and actions to take) to rapidly identify and isolate suspect cases. ☐
- Facility has a process that occurs after a suspect case is identified to include immediate notification of facility leadership/infection control. ☐
- Facility has a process to notify local or state health department of a suspect case soon after arrival. ☐
- Facility has a process for receiving suspect cases arriving by ambulance. ☐

3. Patient placement:

- Confirm the number and location of Airborne Infection Isolation Rooms (AIIRs) available in the facility (ideally AIIRs will be available in the emergency department and on inpatient units). ☐
- Document that each AIIR has been tested and is effective (e.g., sufficient air exchanges, negative pressure, exhaust handling) within the last month. The AIIR should be checked for negative pressure before occupancy. ☐

continue on next page

cont.

- Verify each AIR meets the following criteria:
 - Minimum of 6 air changes per hour (12 air changes per hour are recommended for new construction or renovation).
 - Air from these rooms should be exhausted directly to the outside or be filtered through a high-efficiency particulate air (HEPA) filter before recirculation.
 - Room doors should be kept closed except when entering or leaving the room, and entry and exit should be minimized.
 - When occupied by a patient, the AIR is checked daily for negative pressure.
- A protocol is established, which specifies that aerosol-generating procedures that are likely to induce coughing (e.g., sputum induction, open suctioning of airways) are to be performed in an AIR using appropriate PPE.
- Facility has plans to minimize the number of HCP who enter the room. Only essential personnel enter the AIR. Facilities should consider caring for these patients with dedicated HCP to minimize risk of transmission and exposure to other patients and HCP.
- Facility has a process (e.g., a log, electronic tracking) for documenting HCP entering and exiting the patient room.
- Facility has policies for dedicating noncritical patient care equipment to the patient.

☐☐☐☐☐**4. Transmission-Based Precautions (use Standard, Contact, Airborne Precautions plus eye protection for patients with confirmed or suspected COVID-19 cases):**

- Personal protective equipment (PPE) and other infection prevention and control supplies (e.g., hand hygiene supplies) that would be used for both healthcare personnel (HCP) protection and source control for infected patients (e.g., facemask on the patient) are located in sufficient supply including at patient arrival, triage, and assessment locations.
- Facility has a respiratory protection program. Appropriate HCP have been medically cleared, fit tested, and trained for respirator use.
- HCP receive appropriate training, including "just in time" training on selection and proper use of (including putting on and removing) PPE, with a required demonstration of competency.
- Facility has a process for auditing adherence to recommended PPE use by HCP.

☐☐☐☐**5. Movement of patients with confirmed or suspected COVID-19 within the facility:**

- Patient movement outside of the AIR will be limited to medically-essential purposes.
- A protocol is in place to ensure that, if the patient is being transported outside of the room, HCP in the receiving area are notified in advance.
- Patients transported outside of their AIR will be asked to wear a facemask and be covered with a clean sheet during transport.

☐☐☐**6. Hand hygiene (HH):**

- HH supplies, including alcohol-based hand sanitizer are readily accessible in patient care areas, including areas where HCP remove PPE.
- Facility has a process for auditing adherence to recommended hand hygiene practices by HCP.

☐☐

7. Environmental cleaning:

- Facility has a plan to ensure proper cleaning and disinfection of environmental surfaces and equipment in the patient room. ☐
- If environmental services personnel are given this responsibility, they should be appropriately trained and fit-tested. ☐
- All HCP with cleaning responsibilities understand the contact time for selected products. ☐
- Facility has a process to ensure shared or non-dedicated equipment is cleaned and disinfected after use according to manufacturer's recommendations. ☐
- Facility uses an EPA-registered hospital-grade disinfectant with EPA-approved emerging viral pathogens claims on hard non-porous surfaces. ☐
 - If there are no available EPA-registered products that have an approved emerging viral pathogen claim for COVID-19, products with label claims against human coronaviruses should be used according to label instructions.

8. Monitoring and managing HCP:

- The facility follows the local/state public health authority's policies and procedures for monitoring and managing HCP with potential for exposure to COVID-19, including ensuring that HCP have ready access, including via telephone, to medical consultation. ☐
- Facility has a process to track exposures and conduct active- and/or self-monitoring of HCP if required by public health. ☐
- Facility has a process to conduct symptom and temperature checks prior to the start of any shift of asymptomatic, exposed HCP that are not work restricted. ☐

9. Visitor access and movement within the facility:

- Plans for visitor access and movement within the facility have been reviewed and updated within the last 12 months. ☐
- Visitors are screened for symptoms of acute respiratory illness before entering the hospital. ☐
- Facility has a plan to restrict visitation to rooms of patients with confirmed or suspected COVID-19. ☐
- If visitors are allowed to enter the room of a confirmed or suspected COVID-19 patient, the facility will: ☐
 - Enact a policy defining what PPE should be used by visitors.
 - Provide instruction to visitors before they enter a patient room, on hand hygiene, limiting surfaces touched, and use of PPE according to current facility policy.
 - Maintain a record (e.g., a log with contact information) of all visitors who enter and exit the room.
 - Ensure that visitors limit their movement within facility (e.g. avoid the cafeteria).

10. Facility regularly monitors the situation on CDC's coronavirus disease (COVID-19) web page, www.cdc.gov/COVID19☐

Chapter 483

COVID-2019: CDC PROTECTS AND PREPARES COMMUNITIES*

Department of Health and Human Services

* This is an edited, reformatted and augmented version of Department of Health and Human Services Publication No. CS 315454-A, dated February 25, 2020.

CDC PROTECTS AND PREPARES COMMUNITIES

CDC is aggressively responding to the global outbreak of COVID-19 and preparing for the potential of community spread in the U.S.

For more information: www.cdc.gov/COVID19.

Chapter 484

COVID-19: WHAT TO DO IF YOU ARE SICK WITH CORONAVIRUS DISEASE 2019 (COVID-19)*

Department of Health and Human Services

If you are sick with COVID-19 or suspect you are infected with the virus that causes COVID-19, follow the steps below to help prevent the disease from spreading to people in your home and community.

STAY HOME EXCEPT TO GET MEDICAL CARE

You should restrict activities outside your home, except for getting medical care. Do not go to work, school, or public areas. Avoid using public transportation, ride-sharing, or taxis.

SEPARATE YOURSELF FROM OTHER PEOPLE AND ANIMALS IN YOUR HOME

People: As much as possible, you should stay in a specific room and away from other people in your home. Also, you should use a separate bathroom, if available.

Animals: Do not handle pets or other animals while sick. See COVID-19 and Animals for more information.

CALL AHEAD BEFORE VISITING YOUR DOCTOR

If you have a medical appointment, call the healthcare provider and tell them that you have or may have COVID-19. This will help the healthcare provider's office take steps to keep other people from getting infected or exposed.

* This is an edited, reformatted and augmented version of Department of Health and Human Services, Publication No. CS 314937-D, dated February 24, 2020.

WEAR A FACEMASK

You should wear a facemask when you are around other people (e.g., sharing a room or vehicle) or pets and before you enter a healthcare provider's office. If you are not able to wear a facemask (for example, because it causes trouble breathing), then people who live with you should not stay in the same room with you, or they should wear a facemask if they enter your room.

COVER YOUR COUGHS AND SNEEZES

Cover your mouth and nose with a tissue when you cough or sneeze. Throw used tissues in a lined trash can; immediately wash your hands with soap and water for at least 20 seconds or clean your hands with an alcohol-based hand sanitizer that contains at least 60 to 95% alcohol, covering all surfaces of your hands and rubbing them together until they feel dry. Soap and water should be used preferentially if hands are visibly dirty.

AVOID SHARING PERSONAL HOUSEHOLD ITEMS

You should not share dishes, drinking glasses, cups, eating utensils, towels, or bedding with other people or pets in your home. After using these items, they should be washed thoroughly with soap and water.

CLEAN YOUR HANDS OFTEN

Wash your hands often with soap and water for at least 20 seconds. If soap and water are not available, clean your hands with an alcohol-based hand sanitizer that contains at least 60% alcohol, covering all surfaces of your hands and rubbing them together until they feel dry. Soap and water should be used preferentially if hands are visibly dirty. Avoid touching your eyes, nose, and mouth with unwashed hands.

CLEAN ALL "HIGH-TOUCH" SURFACES EVERY DAY

High touch surfaces include counters, tabletops, doorknobs, bathroom fixtures, toilets, phones, keyboards, tablets, and bedside tables. Also, clean any surfaces that may have blood, stool, or body fluids on them. Use a household cleaning spray or wipe, according to the label instructions. Labels contain instructions for safe and effective use of the cleaning product including precautions you should take when applying the product, such as wearing gloves and making sure you have good ventilation during use of the product.

MONITOR YOUR SYMPTOMS

Seek prompt medical attention if your illness is worsening (e.g., difficulty breathing). Before seeking care, call your healthcare provider and tell them that you have, or are being evaluated for, COVID-19. Put on a facemask before you enter the facility. These steps will help the healthcare provider's office to keep other people in the office or waiting room from getting infected or exposed.

Ask your healthcare provider to call the local or state health department. Persons who are placed under active monitoring or facilitated self-monitoring should follow instructions provided by their local health department or occupational health professionals, as appropriate.

If you have a medical emergency and need to call 911, notify the dispatch personnel that you have, or are being evaluated for COVID-19. If possible, put on a facemask before emergency medical services arrive.

DISCONTINUING HOME ISOLATION

Patients with confirmed COVID-19 should remain under home isolation precautions until the risk of secondary transmission to others is thought to be low. The decision to discontinue home isolation precautions should be made on a case-by-case basis, in consultation with healthcare providers and state and local health departments.

For more information: www.cdc.gov/COVID19.

Chapter 485

THE DEFENSE PRODUCTION ACT (DPA) AND COVID-19: KEY AUTHORITIES AND POLICY CONSIDERATIONS*

Michael H. Cecire and Heidi M. Peters

As the coronavirus (COVID-19) outbreak develops, the United States faces drug and medical supply scarcities due to disrupted supply chains and increased demand. In response, the President may exercise emergency authorities under the Defense Production Act of 1950 (DPA; 50 U.S.C. §§4501 et seq.) to address supply shortages and economic development impacts, and may have begun the process of doing so. This Insight considers DPA authorities that may be used to address domestic essential goods and materials shortages caused by the outbreak, and explores potential policy considerations for Congress. For more information on the health and epidemiological aspects of COVID-19, see CRS products R46219 and IF11421.

DPA PROVISIONS AND RECENT USE

The DPA confers broad presidential authorities to mobilize domestic industry in service of the *national defense*, defined in statute as various military activities and “homeland security, stockpiling, space, and any directly related activity” (50 U.S.C. §4552.) including emergency preparedness activities under the Stafford Act, which has been used for public health emergencies. Many of these authorities are delegated to executive agencies under Executive Order 13603.

Current DPA authorities include, but are not limited to:

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11231, dated March 6, 2020.

- *Title I: Priorities and Allocations*, which allows the President to require persons (including businesses and corporations) to (1) prioritize and accept government contracts for materials and services, and (2) allocate or control the general distribution of materials, services, and facilities as necessary to promote the national defense. Title I prioritization authorities are regularly utilized by the Department of Defense (DOD) to acquire critical military capabilities and less frequently by the Department of Homeland Security (DHS) for disaster response and preparedness needs. The allocations authority has not been invoked since the Cold War, such as to promote energy development in 1974.
- *Title III: Expansion of Productive Capacity and Supply*, which allows the President to provide economic incentives to secure domestic industrial capabilities essential to meet national defense and homeland security requirements. DPA Title III is specifically intended to “create, maintain, protect, expand, or restore domestic industrial base capabilities” (50 U.S.C. §4533). Authorized incentives include loans, loan guarantees, direct purchases and purchase commitments, and the authority to procure and install equipment in private industrial facilities. DOD regularly utilizes Title III authorities and operates a standing DPA Title III program funded by annual congressional appropriations.
- *Title VII: General Provisions*, which includes key definitions and other distinct authorities. These provisions grant the President the authority to establish voluntary agreements with private industry; the authority to block proposed or pending foreign corporate mergers, acquisitions, or takeovers that threaten national security; and the authority to employ persons of outstanding experience and ability and to establish a volunteer pool of industry executives who could be called to government service in the interest of the national defense.

For a more in-depth discussion of DPA authorities, see CRS Report R43767.

DPA AUTHORITIES AND COVID-19

As the DPA’s definition of national defense encompasses homeland security issues, the DPA could potentially be used to respond to public health emergencies, though this has not occurred before. At the President’s discretion, DPA authorities could be employed to address concerns over medical supplies shortages due to the COVID-19 outbreak.

Case Study: Using DPA to Expand Medical Protective Gear Production

As an example of how DPA authorities could be exercised, consider the availability of personal protective equipment (PPE), such as respirator masks, amid the outbreak. Reported PPE shortages may be due to significantly increased consumer demand related to the outbreak itself, and supply chain disruptions resulting from containment measures in China and elsewhere.

Under Title I, the President could prioritize domestic production of PPE to ensure sufficient national stockpiles, and allocate them according to the needs of the emergency. Under Title III, the federal government could use authorized incentives to expand domestic capacity for PPE manufacturing to meet the needs of the emergency. Under Title VII, the President could establish voluntary agreements with private industry—which might normally be subject to anti-trust statutes—to coordinate industry PPE production.

Policy Implications for Congress

The decision whether to employ DPA authorities generally lies with the President. However, in addition to Congress's inherent oversight authority, the DPA statute outlines several specific congressional equities:

1. Title I authorities can only be used for wage and price controls if accompanied by a joint resolution of Congress (50 U.S.C. §4514). This could be applicable in this case in the production and sale of PPE, drug treatments or vaccines, or other necessary goods, and would require coordination between the Administration and Congress.
2. Budget authority for Title III direct loans and guarantees must be specifically included in an appropriations act passed by Congress (50 U.S.C. §4531).
- 3.
4. Title III projects that cumulatively cost more than \$50 million must be authorized by an act of Congress, and the President is required to notify the committees of jurisdiction (the House Committee on Financial Services and the Senate Committee on Banking, Housing, and Urban Affairs), and provide 30 days for comment (50 U.S.C. §4533). A large-scale effort to expand outbreak-related production capacity may require sums far greater than \$50 million.

However, the DPA confers broad waivers to its Title III requirements:

During a period of national emergency declared by Congress or the President; or upon determination by the President, on a nondelegable basis, that action is necessary to avert an industrial resource or critical technology item shortfall that would severely impair national defense capability. (50 U.S.C. §4531(d)(1)(B))

Another area of possible congressional interest is DPA funding, which is appropriated annually. The FY2020 appropriation to the DPA fund was \$64.4 million; the President's FY2021 budget requested \$182 million for the DPA fund (p. 276). DPA appropriations could also be made as part of a supplemental appropriations package if the DPA fund is exhausted and/or to provide resources for other DPA authorities.

Chapter 486

FROM SARS TO 2019-CORONAVIRUS (nCoV): U.S.-CHINA COLLABORATIONS ON PANDEMIC RESPONSE*

Jennifer Bouey¹ and The RAND Corporation²

Chairman Bera, Ranking Member Yoho, and members of the subcommittee, thank you for inviting me to testify about U.S.-China collaboration on pandemic response, especially in light of the recent novel coronavirus outbreak. First, I will describe the 2002–2003 outbreak of severe acute respiratory syndrome (SARS) and the global response. Next, I will discuss U.S.-China collaboration from 2003–2012, followed by developments in the years prior to the current coronavirus outbreak. Lastly, I will analyze the characteristics of 2019-nCoV and China's early responses, and offer policy recommendations.

2002–2003: SARS

Almost 17 years ago, a novel coronavirus was silently causing deadly pneumonia outbreaks—which later became known as SARS—in China. The index case of the SARS outbreak occurred in the city of Foshan in Guangdong Province, China, on November 16, 2002. Neither this case nor a few other cases in December attracted any notice from the public. A public health expert team from the province, which included a few representatives from the national Ministry of Health, went to one of the cities in Guangdong province in January 2003 to investigate. The team concluded that the atypical pneumonia diagnoses were

* This is an edited, reformatted and augmented version of United States House of Representatives Testimony presented before the House Foreign Affairs Subcommittee on Asia, the Pacific, and Nonproliferation, Publication No. CT-523, dated February 5, 2020.

¹ The opinions and conclusions expressed in this testimony are the author's alone and should not be interpreted as representing those of the RAND Corporation or any of the sponsors of its research.

² The RAND Corporation is a research organization that develops solutions to public policy challenges to help make communities throughout the world safer and more secure, healthier and more prosperous. RAND is nonprofit, nonpartisan, and committed to the public interest.

probably caused by a virus. The team then suggested in a “top-secret” report that the provincial health bureau should establish a case-reporting system. This reasonable—although rather feeble—suggestion was expressed in a news bulletin for local health care professionals but fell on deaf ears during the Chinese New Year. The world did not find out for another two months that this was severe acute respiratory syndrome (SARS), a viral pneumonia that would infect more than 8,000 people globally and lead to 774 deaths.

At that time, China lacked a national center for disease control, which would have been responsible for maintaining a robust surveillance system for detecting emerging diseases. It also lacked a national case-reporting system. In addition, according to the *Implementing Regulations of the Law of the People’s Republic of China on Guarding State Secrets* regarding the handling of public health-related information, any occurrence of infectious disease should be classified as a state secret before it is “announced by the Ministry of Health.”³ No physician or journalist can alert the public without breaking the law. With no information from government or media, the Chinese public was unaware of the outbreak until cell phone messages about a “deadly flu” started to circulate in early February 2003 in Guangzhou. A widespread panic caused residents to clear out antibiotics and flu medicines in pharmacies. Prompted by the public panic, the Guangdong health officials finally held a press conference on February 11 to announce the 305 atypical pneumonia cases in the province. China submitted the case report to the World Health Organization (WHO) as *atypical pneumonia*, probably caused by chlamydia or a virus around the same time. Afterward, information about the disease was reported on the news media, but the flow of information stopped on February 23. The news blackout from February 23 continued during the run-up to the National People’s Congress in March, and the government shared little with the public until early April.⁴

Meanwhile, a “super-spreading” chain of transmission emerged at the end of the January and lasted until March, causing international attention on the outbreak: A patient with pneumonia in Guangdong was transferred between three different hospitals, ultimately infecting 200 people, including a doctor from Zhongshan Hospital. The doctor traveled to Hong Kong and infected 12 people in a hotel, and these 12 people then carried the virus to Singapore, Vietnam, Canada, Ireland, and the United States.⁵

By mid-March 2003, SARS clusters started to appear in Vietnam, Hong Kong, Singapore, and Canada. The WHO subsequently picked up the alerts from the Global Outbreak Alert and Response Network (GOARN) and issued a global alert about a new infectious disease of unknown origin. Between March 16 and March 21, the WHO started to suspect that the more than 300 cases from February—which China had labeled “atypical pneumonia” in its report—were actually SARS cases. At China’s request, the WHO sent a team to China on March 23. On March 27, the WHO team concluded that the “atypical

³ Yanzhong Huang, “The SARS Epidemic and Its Aftermath in China: A Political Perspective,” in Stacey Knobler, Adel Mahmoud, Stanley Lemon, Alison Mack, Laura Sivitz, and Katherine Oberholtzer, eds., *Learning from SARS: Preparing for the Next Disease Outbreak: Workshop Summary*, Washington, D.C.: The National Academies Press, 2004.

⁵ Institute of Medicine, “Summary and Assessment,” in Stacey Knobler, Adel Mahmoud, Stanley Lemon, Alison Mack, Laura Sivitz, and Katherine Oberholtzer, eds., *Learning from SARS: Preparing for the Next Disease Outbreak: Workshop Summary*, Washington, D.C.: The National Academies Press, 2004.

pneumonia” cases were same as SARS, and China announced 792 cases and 31 deaths.⁶ Under intense international pressure to mobilize against the pandemic threat, the Chinese government publicly acknowledged the SARS outbreak at the end of March and undertook a series of responsive actions in the following weeks, including

- establishment of new rules requiring all local health officials to report the number of cases daily, with severe penalties for noncompliance
- streamlining of interdepartmental communication and cooperation on the crisis
- creation of national and provincial interdepartmental SARS task forces
- dedication of over \$1 billion to treating the patients and controlling the epidemic.⁷

In late April 2003, China’s health minister and Beijing’s mayor were fired one day after the Chinese Premier announced severe consequences for local officials who failed to report SARS cases in a timely and accurate manner. (That same day, the number of cases in Beijing jumped from 37 to 407.) By the end of May, more than 1,000 officials were fired or penalized for their “slack” responses to SARS.⁸ The remaining officials, driven by political zeal, began to seal off villages, apartment complexes, and university campuses; quarantined tens of thousands of people; and set up checkpoints to take temperatures. A new hospital was built within 20 days in Beijing to accommodate and quarantine SARS patients. The epidemic started to subside in late May. By June 27, the WHO announced that China was “SARS-free.” On August 16, the last two SARS patients were discharged from a Beijing hospital.

SARS revealed the state of China’s unprepared public health system. It led the country to significantly rethink its approach to both domestic and global health. The government soon invested 6.8 billion renminbi (RMB) (850 million U.S. dollars [USD]) for the construction of a three-tiered network of disease control and prevention. The outbreak also spurred China to strengthen its relationships with the United States and the wider international community around issues of public health concerns. The change in China was welcomed and enthusiastically supported by governments and scientists around the world.

2003–2013: U.S.-CHINA COLLABORATIONS AND CHINA’S PUBLIC HEALTH RESTRUCTURING AND CAPACITY-BUILDING

Increased U.S.-China collaboration on global health was an important result of the SARS response. In October 2003, three months after the conclusion of the SARS pandemic, U.S. Secretary of Health and Human Services Tommy Thompson visited China and signed a multiyear partnership with the Chinese Ministry of Health to develop a more robust public

⁸ Huang, 2004.

health infrastructure in China. Thompson also established an HHS health attaché at the U.S. embassy in Beijing. The following month, U.S. Secretary of State Colin Powell noted that

It is upon such concrete forms of cooperation on issues of regional and global importance that a 21st century U.S.-China relationship will be built, issue by issue, experience by experience, challenge by challenge, initiative by initiative, program by program.⁹

H5N1: 2003–2009

Not long after the SARS pandemic, China and the international community confronted another complex challenge with the H5N1 influenza virus—commonly known as “avian flu” or “bird flu” because it infects and spreads largely through birds. Cases of bird-to-human transmission were discovered in Fujian Province in 2003. In 2004, the Chinese National Influenza Center and the U.S. Centers for Disease Control and Prevention (CDC) initiated cooperative agreements to build Chinese capacity in influenza surveillance. The two agencies collaborated on 1) developing technical expertise in virology and epidemiology in China; 2) developing a comprehensive influenza surveillance system by enhancing influenza-like illness reporting; 3) strengthening analysis, utilization, and dissemination of surveillance data; and 4) improving early response to influenza viruses with pandemic potential. In 2005, both governments inaugurated the Collaborative Program on Emerging and Re-emerging Infectious Diseases, which turned into the CDC’s China Center. That same year, both countries established the U.S.-China Health Care Forum to address bilateral commercial, trade, and policy issues relating to health. Additionally, U.S. President George W. Bush announced the International Partnership on Avian and Pandemic Influenza—an ongoing framework for U.S.-China cooperation around the issue—in an address to the United Nations (UN).¹⁰ In 2006, the U.S. Department of Health and Human Services (HHS) and China’s Ministry of Health (MOH) further expanded their collaboration on biomedical research with a memorandum of understanding on research, technology, training, and personnel exchange.

H1N1: 2009

The capacity-building and infrastructure put into place to monitor the continuing threat from avian flu served China and the United States well when another novel influenza strain—H1N1, commonly known as “swine flu”—emerged in 2009. The epicenter was in the United States and Mexico, but the flu soon spread across the globe. American and Chinese health authorities shared information and technology to facilitate national monitoring of H1N1’s spread and to develop a vaccine; China subsequently became the first country to mass-produce an H1N1 vaccine. During the summer lull in the 2009 pandemic, the two countries strengthened their bilateral health communications through the U.S.-China Strategic Economic Dialogue. As then–U.S. President Barack Obama visited China in November 2009

⁹ Colin L. Powell, “Remarks at Conference on China-U.S. Relations,” College Station, Tex., November 5, 2003.

¹⁰ George W. Bush, statement delivered to the 2005 World Summit of the United Nations, High Level Plenary Meeting, New York, September 14, 2005. As of February 3, 2020: <http://www.un.org/webcast/summit2005/statements/usa050914.pdf>.

in the midst of the H1N1 outbreak, the two countries addressed global public health in a joint statement, pledging to “deepen cooperation on global public health issues, including Influenza A (H1N1) prevention, surveillance, reporting and control, and on avian influenza, HIV/AIDS, tuberculosis, and malaria.”¹¹

China’s National Influenza Center Expansion: 2010–2014

From 2010 to 2014, China expanded the Chinese National Influenza Center (CNIC) to include 408 laboratories and 554 sentinel hospitals, and it trained 2,500 public health staff. CNIC became the fifth WHO Collaborating Centre for Reference and Research on Influenza. CNIC established viral drug resistance surveillance and platforms for gene sequencing, reverse genetics, serological detection, and development of vaccine strains. CNIC also built a bioinformatics platform to strengthen data analysis, publishing weekly online influenza surveillance reports in English and Chinese. The surveillance system now collects between 200,000 and 400,000 specimens and tests more than 20,000 influenza viruses annually, which provide valuable information for WHO influenza vaccine strain recommendations. CNIC now provides training for other countries to improve global capacity for influenza control.¹²

H7N9: 2013

CNIC was fully functional when another novel strain of avian influenza, H7N9, emerged in eastern China in 2013. This form of avian influenza has a high fatality rate, of 30 percent (similar to Middle East Respiratory System [MERS]), but human-to-human transmission proved extremely rare, allowing the outbreak to remain in check with effective public health measures.

This time, China quickly reported the new viral strain to the WHO after only three cases were detected, and it also posted the full viral genome sequences of these cases in a public international database to facilitate research around the world. The outbreak plateaued in June at around 130 confirmed cases with more than 40 confirmed deaths, but, as expected, the virus reemerged the following winter, with more than 100 confirmed cases and 20 deaths in China in January 2014 alone.

China’s domestic response to the H7N9 outbreak prevented the virus from spreading beyond mainland China, save for a handful of cases in Hong Kong, Taiwan, and Malaysia. Chinese scientific cooperation with the international community also allowed other countries to prepare for further spread of the virus. Chinese scientists developed a vaccine in October 2013—the first influenza vaccine developed entirely in China—and shared their method with the world, facilitating vaccine development efforts by the U.S. CDC and private

pharmaceutical companies. The Chinese and American CDCs collaborated throughout the H7N9 outbreak by sharing epidemiological data and engaging in joint research on the virus. The Chinese efforts to manage the outbreak of H7N9 were widely praised by governments and scientists around the world.¹³ In the United States, the CDC partially activated its Emergency Operations Center to conduct epidemiological and vaccine research, provide assistance to the Chinese, and develop and distribute test kits capable of detecting the virus worldwide.¹⁴

HIV/AIDS: 2003–2014

Besides preparing for and responding to influenza epidemics, the United States also helped China in its campaign against HIV/AIDs. In 2002, the U.S. National Institutes of Health (NIH) gave the Chinese CDC a five-year, \$14.8 million grant to develop infrastructure to improve research and better monitor the spread of the disease in the country. Beijing also partnered with the U.S. CDC to establish the CDC's Global AIDS Program (GAP) in China in early 2003. GAP quickly developed and implemented a comprehensive HIV prevention and mitigation plan across 15 Chinese provinces to promote increased surveillance of high-risk populations. The CDC, in partnership with China's National Center for AIDS/STD Control and Prevention, has assisted with capacity-building, including the improvement of the quality and geographical reach of laboratory testing capabilities, the development of an epidemiological surveillance system, and the expansion of treatment options. The U.S. CDC has assisted Chinese health authorities with the establishment of three HIV/AIDS clinical training centers in rural areas, which have educated more than 300 graduates who are now providing antiretroviral therapy for 50,000 patients in 16 provinces.¹⁵

2013–2019: The Years Leading Up to the 2019 Coronavirus

Ebola

In 2014, the Chinese government launched an unprecedented response to the Ebola epidemic in West Africa in 2014.¹⁶ China's State Council dispatched one of its largest medical teams of about 1,200 clinicians, public health experts, and military medical officers after the WHO declared a Public Health Emergency of International Concern (PHEIC). The Chinese team opened a 100-bed treatment unit and established three field demonstration sites in Sierra

Leone while providing free treatment. Within six months, China also built a biosafety level 3 laboratory, transporting all construction materials into the laboratory in only 87 days.¹⁷

The United States took similar actions but on a larger scale, with aid exceeding \$1 billion. In some cases, U.S. and Chinese teams collaborated on the ground in Africa. On the international stage, the United States and China worked together at the UN Security Council, jointly declaring the Ebola outbreak a “threat to international peace and security,” and called on governments around the world to respond to the crisis.¹⁸ In June 2015, at the U.S.-China Symposium on Ebola, Research, and Global Health Security hosted by the NIH, both countries renewed their commitment to building systems to detect, prevent, and respond to global health threats.

Indeed, these collaborations between U.S. and Chinese public health agencies are the ones that the 2016 U.S.-China Strategic and Economic Dialogue highlighted as venues for deeper cooperation moving forward: “The United States and China are committed to strengthening cooperation to improve global health security,” both sides agreed. They pledged to further “strengthen their partnership to build capacity to prevent, detect and respond to infectious disease threats including but not limited to influenza, malaria, laboratory capacity, and antimicrobial resistance.”¹⁹

However, a big change in the U.S.-China relationship was on the way. Afraid of western influences, China enacted new legislative restrictions on foreign nongovernmental organization (NGO) activity on January 1, 2017; the law requires foreign-based researchers in China to have a government partner who will report their activities to central and local security agencies. Then, in 2018, due to a U.S.-China trade war, such diplomacy dialogues as the strategic and Economic Dialogue and bilateral diplomatic and security dialogues halted. Subsequently, the United States closed the National Science Foundation office in Beijing in 2018 (along with its offices in Tokyo and Brussels) and the GAP program. Currently NIH and the CDC both reduced their staff in the Beijing office.

In summary, in the 18 years since SARS, with help from the international community and through the commitment of the Chinese government, China has invested in a nationwide network of its own centers for disease control at the national, provincial, prefecture, and county levels; they are connected by a real-time, web-based reporting system for emerging public health events. The workforce for China’s CDCs is large, relative to the 15,000 employees at the U.S. CDC, consisting of 3,481 units and 877,000 public health professional positions at all levels of government. China also has a world-class National Influenza Center. However, the question on the minds of global health organizations around the world is, is China truly ready for the next pandemic?

A report in late 2018 from China’s CDC casts some doubts.²⁰ The challenges, as the authors highlighted, are multifaceted. First, the growing public health needs (and the voids after the departure of international funders) have stretched still-limited investments in China’s

²⁰ One hundred years of Influenza since the 1918 Pandemic -Is China prepared today? CCDC weekly; 2018:1 (4) 56-61.

public health and its preparedness and response. In the past decade, many Chinese agencies have prioritized innovation in technology, including biomedical research. They have also invested in restructuring the health system for the population of 1.4 billion. Public health, in comparison, was relatively underfunded due to these competing priorities. At the local level, local CDCs are supported by provincial governments. In places where the local government's resources are less robust or declining, local public health resources, including personnel, can also suffer from insufficient funding. Low salaries are a significant barrier to the recruitment and retention of high-quality professionals, and local Chinese CDC staffing has declined at all levels. Secondly, suboptimal multisector coordination, such as inadequate communication and inconsistent data sharing between health and veterinarian sectors, between clinicians and public health professionals, can delay early detection of emerging diseases. Insufficient health care surge capacity was also identified as a potential barrier for providing sufficient response to pandemics, as well as the lack of an official technical framework to communicate an epidemic's intensity, severity, and risks to public.

These underlying issues with the Chinese CDC—especially its dwindling funding and lack of effective communication with public and other sectors—may explain the different fate of the two main surveillance systems in China for detecting and monitoring emerging pathogens. One is China's national sentinel surveillance system for influenza-like illness (ILI), as mentioned earlier, anchored by more than 500 sentinel hospitals in 31 provinces.²¹ The other is the national pneumonia surveillance system, which was built and has been maintained by China's CDC since 2004. The latter is designed to monitor pneumonia of unknown etiology (PUE) and facilitate timely detection of novel respiratory pathogens, such as SARS or the 2019 coronavirus. The ILI system is able to use the hospital information system for case recording and outpatient monitoring since the network is hospital-based. The PUE surveillance system, on the other hand, belongs to the CDC system, and has not been used consistently. One study found that 29 percent of community-acquired pneumonia cases that met the PUE criteria were not reported to the PUE system in 2009.²² Only 1,016 PUE cases in all of China were reported during a nine-year period. A study showed that the number of cases surged when an outbreak occurred, either during the SARS outbreak or during A(H5N1) outbreaks. This surge may reflect enhanced administrative requirements from health authorities or enhanced clinician awareness of respiratory viruses.²³ This illustrated that the hospital system (a system paralleled to the CDC system) is in better fiscal condition to maintain a surveillance system compared with the CDC system, which is underused and not sensitive unless it is triggered by an established outbreak.

But a more fundamental question is, what role will China's CDC take in an outbreak response? From what I have witnessed in SARS and 2019-nCoV, the CDC's role is mostly that of consultation rather than decisionmaking.

2019–2020: IS 2019-nCoV ANOTHER SARS?

As millions of Chinese prepared to celebrate the 2020 Chinese New Year, the country was seized by anxiety over the emergence of a rapidly evolving epidemic of pneumonia associated with a new coronavirus, 2019-nCoV. At the time of this writing, more than 17,000 confirmed cases and more than 20,000 probable cases have spread throughout China and 23 other countries, causing more than 360 deaths. After person-to-person transmission was reported in four of the 23 countries known to be experiencing cases of the virus, the WHO declared a Public Health Emergency for International Concerns (PHEIC) on January 29, signaling global consensus on deeming the 2019-nCoV outbreak as an extraordinary public health risk. Therefore, to address the question, "Is this another SARS?" I will provide my thoughts from two angles: (1) Will the 2019-nCoV epidemic be similar to that of SARS? (2) What can we learn from comparing China's current response with that of SARS 18 years ago?

Agent, Host, Environment, and Transmission

2019-nCoV is the latest member of the coronavirus family. This type of virus is commonly found in humans and other mammals, such as bats, civet cats, and camels. In humans, coronavirus has four strains that cause mild clinical symptoms, usually referred as the common cold. Two other strains are more lethal: SARS and MERS. Currently, I do not know whether the new virus will cause clinical symptoms similar to the strains that cause the common cold or to the two strains of coronavirus that caused large-scale epidemics and fatalities. We do know that it shares a high degree of genomic similarity to coronavirus in bats, and to SARS-CoV in humans.²⁴ It is as contagious as SARS, but so far, the reported statistics indicate a lower proportion of case fatalities (around 2–3 percent) compared with SARS (10–14 percent) and MERS (35 percent).²⁵ The severe symptoms and fatalities seem to be associated with individuals with medical complications. These estimates can change if the virus continues to mutate or the data are, in reality, different from what we know. For now, the moderately high infectivity, mild clinical symptoms, and wide-ranging incubation period may mean that the novel virus is less harmful to individuals but may coexist with humans and become endemic. In this sense, 2019-nCoV has the potential to cause a pandemic.

The physical and social environments of 2020 are also very different from those in 2002.

²⁵ Chen Wang, Peter W. Horby, Frederick G. Hayden, and George F. Gao, "A Novel Coronavirus Outbreak of Global Health Concern," *The Lancet*, January 24, 2020.

China is wealthier and more globalized today. Today, there are 739 international air travel routes originating from China—three times the number of routes (233) available in 2002. On average, 51 million people travel between China and another country per year, a number many times higher than the 3 million back in 2002. The epicenter of the outbreak, Wuhan, is a major transportation hub in central China, sometimes known as “Chicago of China.” On an average day, 30,000 people fly out of the city, and many more use the bullet trains from three railway stations in the city. The outbreak began right before the Chinese New Year, a time during which more than three billion trips typically occur under normal circumstances. January is also the time when students from overseas colleges to return to school after the winter break and students from Chinese universities start the winter break. The environmental difference between the 2019- nCoV epidemic and SARS is the scale of mobility, which makes the global spreading of the disease much easier than that for SARS.

Prevention and treatment methods are similar between SARS and 2019-nCoV. In both cases, vaccine development takes months to a year and can hardly be helpful in stopping the outbreak. Quarantines, travel bans, and case-tracing can slow down the disease transmission and buy precious time for countries to plan their responses, but they are not perfect prevention methods.²⁶ Quarantine will only be effective if it can guarantee stopping people’s mobility, which is hard to do for a city of 11 million people. Early detection is conducted using proper reverse transcription polymerase chain reaction (RT-PCR) testing kits, thanks to the Chinese scientists who have isolated the novel virus, conducted genomic sequencing, and shared the data with the world in an astonishingly short amount of time. This has helped to identify the virus and has enabled China and other countries to develop effective testing kits for early detection. The treatment of 2019- nCoV mostly focuses on supportive therapy, but a few antiviral medicines are being used experimentally.

The Chinese Government’s Response to 2019-nCoV

The Chinese government’s response to 2019-nCoV has followed a similar pattern to that of the SARS outbreak and is characterized by three common features: (1) delaying public acknowledgement of a public threat, (2) downplaying the severity of the outbreak in its early days, and (3) relying on quarantine, social control, and large-scale health care system mobilization to stop the outbreak. The current response also has a few major differences, including the use of social media, better research, and technology, which have helped mitigate some of the negative effects.

The first common feature response of SARS and 2019-nCoV is the delay in acknowledging the initial case cluster to be a public health threat. If we recognize that stability is what the Chinese political system values most, and an acute public health threat, such as an epidemic, is precisely the “black swan” that can threaten such stability, then it is not too difficult to understand the Chinese government’s reluctance toward acknowledging an epidemic. China’s law prohibits anyone from talking about a public health threat before an official government announcement. For the government to make an announcement on an epidemic, a full process of upward reporting and verifying at every political level has to be

²⁶ Jennifer B. Nuzzo, “Past Epidemics Prove Fighting Coronavirus with Travel Bans Is a Mistake,” *Washington Post*, February 2, 2020.

accomplished. Once the verified report reaches the Ministry level, a special expert group is often sent to investigate. Following such a process, a timely acknowledgement of an epidemic to the public is almost impossible. The exception has been when social stability itself is being threatened. For example, we saw Guangdong government officials breaking the silence three months after the first SARS case only when the public panicked after seeing phone messages regarding a deadly flu in February 2003. We also saw Wuhan health officials announcing the 27 cases of 2019-nCoV on December 31, 2019 after a few doctors in Wuhan sent WeChat messages warning their acquaintances about a “SARS-like” pneumonia. (The informants were later publicly reprimanded by the government.) In this case, wide use of social media, no matter how closely monitored, helped the local officials significantly shorten the waiting period that is usually required for an official announcement.

The second characteristic of the government’s response is the downplaying of the severity of the threat at the beginning of an epidemic. For SARS, the results from the first investigation did not alarm the Ministry—and therefore, there was no public announcement—in January 2003. For the next two months, the government continued downplaying the severity of SARS to the public until the Minister of Health was fired in April. In this recent response to 2019-nCoV, the first expert team went to Wuhan in January 2020 and concluded that there was no person-to-person transmission and the outbreak was well controlled after the closing of the seafood market where many cases (not all) were identified. For days, the local health officials assured the public that there were no new cases in Wuhan and no cases outside Wuhan. This inaccurate portrayal of the disease may have allowed sufficient time for the virus to be spread widely in Wuhan, to other cities in China, and to the world. It was not until the 2019-nCoV cases were confirmed in Thailand and Japan in patients who had had no exposure to the seafood market that the MOH sent a second expert group to Wuhan on January 19. This time, person-to-person transmission was immediately confirmed, and the national case reporting system was triggered on January 20. Although the downplaying of the severity of the epidemic did occur, this time it only lasted 20 days, compared with the 2.5 months during the SARS outbreak. This was due to better biomedical and research capacity of the Chinese researchers in 2019. Chinese scientists were able to quickly culture the virus and share the genomic sequencing data with international researchers by January 11. The genetic sequencing data helped many countries quickly develop testing kits for early detection of the disease. When cases showed up in Thailand and Japan, international genomic researchers were able to quickly identify the matching genomic patterns and confirm the presence of 2019-nCoV. This success helped provide the evidence for understanding the greater geographic spread of the epidemic and the role of person-to-person transmission. During the SARS epidemic, however, because of the lack of virus identification, China’s pneumonia outbreaks were not linked to those in Hong Kong and Vietnam until four months after the index case happened.

Finally, during SARS, once the government finally geared up to stop the outbreak, they swiftly initiated a quarantine policy. With 2019-nCoV, the decision on quarantine was made three days after the government accepted the fact that the outbreak was fueled by person-to-person transmission. This time, the scale of the quarantine was unprecedented. The mayor of Wuhan announced that the government would shut down all public transportation, including airports and railways, in Wuhan—a city of 11 million people—on January 23, two days before the Chinese New Year. The national government also employed social policing to

enforce self-quarantine, canceled public events, and prohibited crowd gatherings across the country.

Without a vaccine, a quarantine is one of the few effective ways to prevent disease transmission. China's decision on a city lockdown has been praised by the WHO and probably buys precious time for many other countries to activate their public health responses. However, there are debates on the effectiveness of the lockdown over such a large area. First, some would argue that by issuing a lockdown only two days before the Chinese New Year, the government missed many people who had left earlier, since new year travel usually starts a week before the new year. The lockdown also took effect a day after the announcement, and many people from Wuhan rushed to get out of Wuhan before it started. As the mayor of Wuhan mentioned in a news conference on January 27, about five million people had left Wuhan by then.²⁷ Second, the lockdown of a city of 11 million people made it harder to implement the typical door-to-door or community-by-community screening, assessment, and provision of supportive care that usually happens after a quarantine is established. Quarantine may also bring heightened fear and stigma among the affected population, accelerate the shortage of medical supplies and health care resources, and provide a false picture that the epidemic is under control. In addition, the economic impact of the quarantine can be large.

SARS cost the world 40 billion USD and China 1 percent of its GDP in 2003. China may suffer more economic loss this year due to the 2019-nCoV, given that quarantine was initiated before the Chinese new year and at a relatively early stage of the epidemic. (Quarantine may last longer than two months.) In 2003, the industries hurt most were tourism, retail, and entertainment, which was 43 percent of China's GDP. Today, these industries account for 54 percent of the GDP.²⁸ China now contributes 17 percent of world's economy, compared with 4.3 percent in 2003, when the SARS epidemic was unfolding. China's current stature in the world economy means that the impact of 2019-nCoV outbreak is likely to substantially exceed that of SARS.

Currently, the national case report system is in use, and the case numbers have surged in the last weeks. However, given that many hospitals in China are overwhelmed by the large volume of people with cold-like symptoms coming for testing and treatment because of the fear of the epidemic, patients are often being turned away, and delayed diagnosis and deaths that are not counted (when infected people die before the diagnosis or at home) are both possible. The two new 1,000-bed hospitals that China built in two weeks may help relieve the severe shortage of hospital beds and improve health care for many infected people. It may also help improve the accuracy of the epidemic's statistics.

In summary, the 2019-nCoV is the third of its type, after SARS and MERS, to cause a global outbreak. The Chinese government's response to 2019-nCoV has been similar to that of SARS; however, the initial delay and the "downplay" time were much shorter this time due to the widespread use of social media and the much-improved local research capacity. The unfolding battle against this new pandemic, meanwhile, highlights the importance of

transparency and open collaboration among scientists globally. It is a reminder that all nations should prioritize and protect global health research, capacity building, and cooperation.

RECOMMENDATIONS

Given that my fellow panelists both have more experience on leading pandemic preparedness programs in the United States, I will focus my recommendations on the China-related issues. I have short-term, medium-term, and long-term suggestions.

Short Term

First, China is on the front line of a full-fledged battle with the new coronavirus. Health care workers are exhausted, and testing kits and personal protection, such as face masks, goggles, and gloves, are all in short supply and have been rationed.²⁹ At this time when many Chinese people are suffering from illness, anxiety, and uncertainty, it is important and opportune for U.S. public health and health care professionals to reach out to China and provide humanitarian and technical aid. Such support will boost the morale of their Chinese colleagues, serve as an international witness to the health care professionals' work at the front line of the epidemic, and help provide technical support on trials of the latest antiviral medicines. I am quite encouraged to hear that the U.S. CDC office in Beijing will be hosting a medical team in the near term.

Secondly, any efforts by the U.S. government to reduce stigma and unfriendly gestures toward people from China and Wuhan at this tense and sensitive moment will increase the soft power of the United States and bring more goodwill from Chinese people toward the United States. Conversely, stigma, prejudice, and any punitive remarks will preclude any sense of goodwill and will also more likely undermine the level of transparency the Chinese government is willing to allow now.

Finally, given that the WHO has declared 2019-nCoV a PHEIC, there are concerns regarding developing countries that do not have a health care system capable of stopping the spread of the virus. In the worst-case scenario, the epidemic may affect more people in these countries when the epidemic subsides in China and the United States. The U.S. CDC may consider working with China's CDC and the China International Development Cooperation Agency (CIDCA) to map out potential collaborations to help these countries in distress.

Medium Term

Once the epidemic is under control, studies on the country response systems and global pandemic management will begin. It might be valuable for the United States to help lead the evaluations with government officials and scholars from China and other countries. There

²⁹ Rosie Perper, "As the Wuhan Virus Spreads, Doctors in the City Say They Face a 'Flooding' of Patients and Not Enough Protective Gear," *Business Insider*, January 24, 2020. As of February 3, 2020: <https://www.businessinsider.com/wuhan-coronavirus-doctors-wuhan-patients-protective-gear-2020-1>.

will be several questions for China to contemplate: What can China do in the future to improve communication about new public health threats? What can be done to increase the transparency about the occurrences and the severity of the outbreak? To what extent are quarantines effective, and how should they be implemented? How can China make its CDC more sustainable and improve multi-sector communications? The lessons learned will benefit not only China, but also other countries that encounter similar issues.

To take such a leadership role, I hope the U.S. government can build a realistic and consistent policy about future U.S.-China collaboration on global health and seek consensus with China on what data to share and what rules to follow.

Long Term

As I mentioned earlier in my testimony, during most of the years between SARS and 2019- nCoV, the United States and China were working side by side to confront the challenges of epidemics. In doing so, both countries have benefited from capacity building for their current and future public health workforces. In our current situation, as the first phase of the trade war is resolved, this could be an opportune time to restart the U.S.-China dialogues on economy, diplomacy, and security. I hope U.S.-China collaboration on global health and pandemic preparedness will benefit from these future talks between the two countries.

Chapter 487

LESSONS FROM THE WEST AFRICAN EBOLA RESPONSE: HOW TO SAVE LIVES AND PROTECT OUR NATION DURING THE NOVEL CORONAVIRUS EPIDEMIC OF 2020*

Ronald A. Klain

Chairman Bera, Ranking Member Yoho, other members of the Subcommittee:

Thank you for inviting me to participate in this hearing today. I want to commend the Subcommittee for moving quickly to gather information and educate the public about the novel coronavirus epidemic that originated in Wuhan, China, and has now spread to countries around the world, including our own. It is a privilege to be able to present my perspective on this, and to answer your questions about the emerging US response.

Before I begin my substantive presentation, I want to make two preliminary points.

First, as frustrating as it may be, it is important to understand that what we know about this epidemic and the virus that causes it remains uncertain and preliminary. We know much less about coronavirus today than we did about Ebola in 2014. Scientists in the US and around the world are working at unprecedented speed to improve our understanding about the virus and its spread; new papers are being published every day, literally. Nonetheless, there are critical questions about the virus, how quickly it spreads, how infectious it might be, how lethal it will be – and others –for which we still do not know the answers, and that (once learned) will have huge impacts on our response. Part of this is due to a lack of full transparency and cooperation by the Chinese government, which hopefully will improve. But part of this is simply due to the fact that it takes time for science to learn key facts about a novel virus. As someone who has coordinated the policymaking and implementation of a response to an epidemic, I know that these information gaps are vexing: many decisions cannot wait, and have to be made on the best information available. But it is important that we understand this limitation, understand that policy choices will have to change as our fact

* This is an edited, reformatted and augmented version of Testimony before the Asia, Pacific and Non-Proliferation Subcommittee of the House Committee on Foreign Affairs, dated February 5, 2020.

base changes, and that we be careful not to make definitive or declarative pronouncements when the science does not justify such statements.

Simply put, at present, we do not know how serious this epidemic will become, how many people – in China, in the US, and elsewhere – will contract the virus, how many will die, and how grave the threat is to our own country. Such a lack of knowledge does not counsel a lack of action, indeed, perhaps it counsels just the opposite. But it does advise modesty in the forcefulness of our conclusions, and awareness of the need to make changes in policy choices as we gain more information.

Second, a point about partisanship and the response. I am an outspoken political partisan – that is well known. But I come here today in the same way that I approached my tenure as White House Ebola Response Coordinator: putting partisanship and politics aside. The coronavirus will not ask any person's partisan affiliation before infecting them. There is no Democratic or Republican approach to fighting infectious disease; only sound and unsound measures.

To reinforce this point: what we did during the Obama administration's Ebola response relied heavily on lessons learned and expertise acquired during the Bush administration's efforts to fight AIDS and malaria in Africa. Key players in the Ebola response were veterans of both Democratic and Republican administrations. President Obama's emergency funding package passed this House with strong, bipartisan support; our implementation of it domestically involved work with state and local officials from both parties, and the input of Members of Congress of all political and ideological camps. Saving lives, abroad and at home, turns on putting politics aside and allowing science, expertise, and sound decision making to govern our actions.

With these two preliminary points made, I want to move on to the subject of my testimony today: how the lessons we learned during the Ebola response in 2014-15 should shape how our government – in the Executive and Legislative branches – approaches the threat now posed by the novel coronavirus.

To be clear, the Ebola response was not without its own problems and mistakes. Particularly early on, the danger to Africa and the world was underestimated; early signs of progress in containing the disease in the Spring of 2014 led to a false sense of security. The fact that no Ebola outbreak prior to 2014 had ever involved more than 500 cases of the disease also led to a false confidence that a large-scale epidemic was unlikely. Early initiatives in West Africa lacked a full understanding of the complexities of implementation there and cultural and religious barriers to some aspects of the response. And confusion and a lack of preparation led to missteps when the first case of Ebola arrived in Dallas, Texas, in late September, 2014.

But ultimately, the US got the response organized; quickly adapted and improved its approach; and made adjustments to what responders were doing in Africa and here at home. President Obama mustered an all-of-government response to the challenge, authorized the first-ever deployment of US troops to combat an epidemic ("Operation United Assistance"), appointed me to lead a team of dedicated and talented professionals at the White House to coordinate this effort, implemented novel and innovative policies on travel screening and monitoring, and worked with Congress to enact a \$5.4 billion emergency package to fight the disease abroad and improve our preparedness at home and around the world for future such epidemic threats.

In the end, the epidemic in West Africa was tragic: an official death toll of over 11,000, with the real count likely higher. But the backdrop for this loss of life must be considered. In September of 2014, experts forecast that the death toll could be over 1 million people; thus, the response succeeded in helping to reduce the projected loss of life by as much as 98%. America's actions – as part of a global response, with Africans playing the largest part, deserving the greatest credit, and suffering the harshest losses to its health care workers – saved hundreds of thousands of lives. It was a great humanitarian achievement.

Here at home, after the initial missteps in Dallas, no one contracted Ebola on US soil, and Americans evacuated for medical care in the US were successfully treated and released, with only a lone fatality. Once implemented, our monitoring system successfully insured no domestic transmission of the disease, routed suspected cases to prepared medical facilities before those patients could be infectious, and enabled ample time for successful testing and response.

The ongoing legacy of this response is likewise enormous. With Congress' support, we implemented a national four-tiered network of hospitals and medical facilities that remain prepared to this day to identify and isolate cases of dangerous infectious disease, and to provide treatment to those who are infected – nothing like this existed in 2014 when the Ebola epidemic began, as many earlier investments made after the anthrax attacks in 2001 had been allowed to dissipate. The capacity to test for and promptly identify diseases like Ebola grew from three laboratories in the US in September 2014 to almost 100 by the end of that year. We developed rapid diagnostics that ended the risky practice of having patients wait days to learn if they were sick and/or infectious. Vaccines against Ebola were tested and developed, and as a result of that work, an effective vaccine now exists and is being used in the field. New therapeutics were developed that helped reduce the mortality rate of Ebola dramatically.

It is no wonder that this effort – without in any way minimizing the devastation in West Africa – is seen today as a huge success. Tom Friedman wrote last year that that West African Ebola response was:

“[President Obama's] most significant foreign policy achievement, for which he got little credit precisely because it worked — demonstrat[ing] that without America as quarterback, important things that save lives and advance freedom at reasonable costs often don't happen.”

From mid-October 2014 to mid-February 2015, I was proud to lead the team at the White House that coordinated this response. We saw the weekly new case count in West Africa drop from about 1,000 a week to fewer than five a week, at which point the President announced the end of Operation United Assistance and began the withdrawal of US troops serving in that mission.

This was a truly global response, with tremendous contributions by government officials, NGOs, and volunteers from around the world, with a particularly close partnership with our allies in the United Kingdom and France. With regard to the US part of this global effort, special thanks should go to the men and women on the frontlines. This includes members of the 101st Airborne (who constituted the bulk of Operation United Assistance), and also, civilian responders -- via US AID DART teams and CDC employees deployed to the region, and contractors who supported them. It includes the men and women of the US Public Health Service who staffed the Monrovia Medical Unit in Liberia. It includes career Ambassadors and other diplomats who served in all three effected countries with skill and played such a

large role in the response. It includes the doctors, nurses and other health care workers – many of them volunteers -- who served in Ebola treatment units, hospitals, and other facilities – treating the sick under extreme conditions. It includes the scientists of the NIH and the CDC who pioneered new diagnostics, therapeutics, and vaccines. The US response put over 10,000 people – soldiers and civilians, government workers and NGO teams, contractors and volunteers – on the ground in West Africa in 2014-2015. It was a gargantuan undertaking, and a story in which all Americans should take pride.

To make that effort effective, and to match it with preparation and protection here at home, it took talented teams in Washington, in Atlanta at the CDC, and in government agencies and private health care facilities around the country. Public servants of all ranks and all levels worked around the clock. And as I mentioned before, Congress acted swiftly and on a bipartisan basis to approve most of the Obama administration's request for \$6 billion in aid, less than five weeks after it was sent to Capitol Hill.

I would be remiss if I did not say that, of course, President Obama, too, deserves credit for this success. He weathered sharp criticism for his actions during the Ebola response, and had to ignore pressures to put aside the advice he was getting from top scientists and medical experts. He made difficult decisions about the actions we took abroad and at home. He communicated openly and directly with the American people, and chaired repeated meetings of the National Security Council as the response took shape. He used every tool at his disposal – from his bully- pulpit (to destigmatize survivors by publicly hugging Ebola patient Nina Pham in the Oval Office after her discharge from the hospital), to authorizing the massive deployment to West Africa, to personally engaging numerous world leaders to activate their resources and support for the response, to urging Congressional leaders to approve his emergency spending package, and much more: he did so much to achieve these results.

The challenge we face from the novel coronavirus that began in China late last year contains many similarities, but also, many differences from the challenge posed by the Ebola epidemic in West Africa in 2014-15. It would be a mistake to simply repeat what we did at that time, given those many differences. But likewise, it would also be a mistake to ignore the lessons that can be learned from that response, given the similarities. And hence, I am grateful for the opportunity to talk about the lessons I think are most applicable from this experience, to be applied in the current circumstance.

Among the many possible lessons that should be employed now, there are seven in particular that I would like to call out today. I will do so briefly, but I am happy to go into more depth on any of them in response to your questions or any subsequent follow-up from the Subcommittee.

First, in a complex, rapidly evolving scenario like the one we are seeing, there is no substitute for White House coordination and leadership. There should be a single official inside the National Security Council at the White House, supported by an appropriate team, working on this full-time, overseeing our response.

This does NOT mean that we need a “Coronavirus Czar” to serve the same role that I played during the Ebola epidemic. At the end of my tenure as Ebola Response Coordinator, I said, in fact, there should never be another specific “Disease Czar” at the White House. Instead, I recommended to President Obama that he create a permanent “Pandemic Preparedness and Response Directorate” inside the NSC, led by a Deputy National Security Adviser-level appointee with direct access to the President as needed, to oversee ongoing

work to prepare for future infectious disease threats, and to coordinate a response when such threats arrive.

President Obama accepted this recommendation, and set up such a unit in 2015. President Trump continued with the structure, and named Admiral Tim Ziemer – a respected long-time public servant – to fill this post. If Admiral Ziemer were still in place, I believe that America would be much better positioned to respond to the coronavirus threat today.

But unfortunately, in July of 2018, when John Bolton took over as head of the NSC, he disbanded this unit, and Admiral Ziemer was reassigned to US AID. As a result, there has been no special unit at the NSC to oversee preparedness for epidemics, or the current response. In addition, the Trump administration has dismantled the Homeland Security Advisor structure that Presidents Bush and Obama used to deal with complex transnational threats, further undermining our preparedness for events like these.

The administration's recent decision to create a "Task Force" to oversee the response, led by Secretary Alex Azar, is a valuable step, but an insufficient one. This is not a criticism of Sec. Azar, who I believe is playing a critical role in the response, and brings great experience and judgment to this effort. But a response to a challenge like this one requires action from a number of federal agencies outside of Sec. Azar's authority: Homeland Security, State, US AID, Transportation, DOD – and probably also Labor, Commerce and Justice. Given the nature of Cabinet government, the fundamentals of bureaucratic behavior, and the realities of competing demands on a Cabinet secretary's time, no single Cabinet agency head can lead such a response. There are global implications as well: in dealing with other nations as the world shapes and implements the response, a single point of coordination inside the White House both emphasizes the response's importance to the President, and facilitates high-level government-to-government cooperation.

For these reasons, and many more, an effective response to a challenge like coronavirus should be led by a full-time, high-level appointee at the White House. Ideally that decision would be made by the Executive Branch, but another avenue to achieve this structure would be for Congress to move ahead on the Global Health Security Act (HR 2166), introduced by Reps.

Connolly and Chabot, as that bill would create much of this apparatus by statute.

Second, the US must "lean forward" to fight this epidemic overseas, using all of the tools and leverage that it can commit to the effort. Unlike West Africa in 2014, China in 2020 probably does not need, and would not accept, thousands of US responders on the ground treating patients, testing new approaches, conducting research, providing infrastructure, and helping bring the disease under control. This is a huge difference.

But that should not get us off our toes, or have us sitting back and believing that our only sphere of action is the homeland. Dr. Tony Fauci of NIH has publicly urged the deployment of medical researchers and investigators to China, and key administration leaders – at State and the White House – should apply pressure to encourage the most open access possible. Nations less advanced or well-resourced than China may experience significant coronavirus outbreaks and require more direct forms of US assistance, akin to what we provided during the 2014 Ebola epidemic, albeit on a smaller scale. We should send CDC experts wherever they would be helpful, and task US AID to determine where DART teams and other assistance could be usefully deployed. Likewise, we should bolster preparedness in low-income countries now – before the disease spreads further – to avoid spread in places where local containment efforts might fail.

Our diplomats should be empowered and engaged around the globe, and our government must press WHO – with stronger leadership today under Dr. Tedros Adhanom Ghebreyesu than it had during the 2014 Ebola epidemic – to do the right thing.

This is a global challenge, and America must provide global leadership. There is no room for isolationism or withdrawal. The best way to keep Americans safe is to contain and combat the virus overseas. We should do this not only because it is generous or humanitarian – though it would be generous and humanitarian, both great American traits – but because it will make America safer and reduce the risk of a larger outbreak here.

Third, the administration must ensure that science and expertise guide our actions, not fear or politics. One of the first casualties in an epidemic is rational thinking, replaced by fear, bias and poor decision-making. We saw this in 2014 with calls for needless travel bans and baseless quarantine restrictions; President Obama was right to reject these misguided calls, and to implement travel and monitoring policies based on the scientific advice he got from the nation's leading experts.

Travel warnings and advisories make sense in the face of the coronavirus; telling people not to take trips to China right now, except in special or compelling cases, is wise. That is quite different from banning people – including, for example, Americans in China, or family members of Americans – from coming back home, or going for essential purposes. Congress should press the administration for the science behind recently announced quarantines and exclusions of non-US persons from travel to the US; also, it should inquire as to the effectiveness of the measures being implemented. Banning travel to or from China altogether would impede the flow of medical assistance, expert investigation, or other key response functions; in addition, key supplies – including supplies critical to our own health care system – come from China.

More generally, there will be many policy decisions to be made in the days and weeks ahead. Science, medicine and expertise should guide them. The American people are lucky to have the world's leading experts on infectious disease working in their government, led by men and women like Tony Fauci at NIH and Anne Schuchat at CDC. They have served Democratic and Republican administrations, and helped Presidents with a wide variety of political perspectives save lives and protect our nation. This expertise should be paramount in decision making at all levels of government.

Fourth, the administration should quickly assemble, and transmit to Congress, an emergency funding package to ensure that there are no delays in responding to the coronavirus challenge. Fighting the coronavirus overseas and at home will cost money. HHS (and its units like ASPR, BARDA, NIH and CDC), US AID, DHS, and other agencies will have costs. State and local governments will feel a pinch from monitoring contacts of those who have the virus, and tracking and monitoring individuals who have been in effected countries. Hospitals treating patients with the virus may need assistance. Research and deployment of new therapeutics and vaccines needs government support, and funding for private-public partnerships. The list of needs goes on.

While Congress responded quickly to a funding request from the Obama administration for Ebola, even that short delay had some impact on our response. The delay of months in approving funding for the Zika response was quite consequential. Most importantly, Congress is unlikely to even begin considering these funding needs until the administration makes a request.

The Trump Administration has tools that we lacked in 2014, most importantly – and to the Congress’ credit – it has a new Emergency Fund on which the Administration can (and has) drawn. But I expect that this will not be adequate, and it would be wise for the administration to begin putting together a Supplemental Funding request immediately.

Fifth, Congress must do its own work in dealing with the novel coronavirus. The burden of action does not rest entirely with the Executive Branch; Congress too must do its part.

This starts with the point I made above: once the administration makes an emergency funding request, Congress should act on it without delay. Of course, Congress should not rubberstamp the request: any proposal to use public funds should get scrutiny and review. But prompt action must drive this process, and divisions between parties or chambers should not result in delay. Indeed, Congress might want to begin now – given the expertise of many in this body – preparing for such a request even before it is made, and contemplating the likely funding needs.

But Congress’ role does not end with acting on the emergency funding question; there are a number of other elements of the response that demand Congressional attention. Hearings like today’s are important, to help ascertain how the response is going and where it needs to be improved. Congress wisely funded the Public Health Emergency Fund last year – but did so only on a limited basis. Adding to that funding, and funding an additional emergency fund specific to the development of therapeutics and vaccines via public-private partnerships, should be considered.

Additionally, as I wrote in the *Post* with Dr. Syra Madad in December – before the coronavirus hit -- Congress is overdue to renew the funding for the network of “Ebola and Special Pathogens Hospitals.” This network was created during the Ebola epidemic in 2014, and funding for it expires in May of 2020. Pending legislation would fund only the 10 most advanced such facilities, and would end federal funding for the 60 other hospitals that screen, test, and provide initial treatment for these cases. Allowing this funding to expire in May would be a huge mistake; funding for these specialized facilities should be renewed, and the network should be strengthened with greater help for frontline facilities, EMS responders, and other touch points in our medical system that are least prepared and most exposed.

Sixth, both the Executive Branch and the Congress should take this as a wake-up call to finish the work we need to do on pandemic preparedness and readiness. Recently, America marked the 100th anniversary of the single largest mortality event in our history: the Spanish Flu epidemic of 1918-19. More Americans died from this epidemic than from World War I, World War II, the Korean War, and the Vietnam War - -combined. While, on the one hand, science has made great strides since 1918, on the other hand, increased global travel, human incursion on animal habitats, and the stresses of climate change have raised the risk that we will face such a “great pandemic” once again.

At present, it seems very unlikely that the coronavirus poses such a threat to the United States – but we cannot know for certain. Moreover, even if this current epidemic is not “the big one” that is coming, it is a reminder that this danger lurks, and our preparedness for it is lacking. As Dr. Ashish Jha of the Harvard Global Health Institute often says, “Of all the things that can kill millions of Americans quickly and unexpectedly, an epidemic is probably the most likely ... and the one in which we invest the least to prevent.”

The Global Health Security Agenda, legislation such as HR 2166, Blue Ribbon Commission reports, table top exercises, proposals from members of this Subcommittee – and my own extensive writing over the past five years – have set forth detailed agendas of what

we need to do to prepared for this event. These bipartisan calls for action have largely been ignored. The current public focus on infectious disease generated by the coronavirus should spur us into action. The time to act on this agenda is now. If we wait until the catastrophic pandemic arrives, it will be too late.

Seventh, we need to be on the watch for discrimination against people in our country of Chinese origin and ancestry, and speak out strongly against any such fear-driven racism. The coronavirus strikes humans – not people of any particular ethnicity or race. Chinese-Americans or Chinese people in America are no more likely to get the disease, carry the disease, or transmit the disease, than any other group of people.

Yet we have already seen signs that such people are the targets of discriminatory fear – with some already being hassled, threatened with expulsion from schools and other mistreatment. As fears of the coronavirus accelerate, so too will these incidents. This kind of discrimination not only is wrong, but also makes it harder to combat the disease. If some members of the Chinese-American community feel that they are likely to face hostility, they are less likely to work closely with authorities, and less likely to heed advice of public health experts.

It is incumbent on every person in authority in this nation to speak out against such racism, and to ensure that this does not become part of our civic life during the coronavirus epidemic.

Americans need to pull together to fight a disease, not pull apart to fight one another.

In closing, I want to thank, again, the Subcommittee for holding this hearing, and for inviting me to participate. I stand ready to answer your questions about any of these points, or any other aspects of the response.

America has the tools, the talent, and the expertise to combat the coronavirus, both abroad and at home. The question now is whether our leaders, in the Executive Branch and the Congress, will deploy them effectively; act promptly and wisely; rely on expertise – not bias and fear; organize and implement our response appropriately; and allow science and medicine to be our touchstone. For the sake of people around the world, and for the sake of the American people, let us work to see that it is so.

Chapter 488

**THE STATE OF U.S. PUBLIC HEALTH
BIO-PREPAREDNESS: RESPONDING TO BIOLOGICAL
ATTACKS, PANDEMICS, AND EMERGING INFECTIOUS
DISEASE OUTBREAKS***

Subcommittee on Oversight and Investigations

FRIDAY, JUNE 15, 2018

HOUSE OF REPRESENTATIVES,

SUBCOMMITTEE ON OVERSIGHT AND INVESTIGATIONS,

COMMITTEE ON ENERGY AND COMMERCE,

Washington, DC.

The subcommittee met, pursuant to call, at 9:01 a.m., in room 2123, Rayburn House Office Building, Hon. Gregg Harper (chairman of the subcommittee) presiding.

Present: Representatives Harper, Griffith, Burgess, Brooks, Collins, Walberg, Walters, Costello, Carter, Walden (ex officio), Degette, Schakowsky, Castor, Ruiz, and Pallone (ex officio).

Also Present: Representative Eshoo.

Staff Present: Jennifer Barblan, Chief Counsel, Oversight and Investigations; Adam Fromm, Director of Outreach and Coalitions; Ali Fulling, Legislative Clerk, Oversight and Investigations, Digital Commerce and Consumer Protection; Christopher Santini, Counsel, Oversight and Investigations; Jennifer Sherman, Press Secretary; Alan Slobodin, Chief Investigative Counsel, Oversight and Investigations; Austin Stonebraker, Press Assistant; Christina Calce, Minority Counsel; Jeff Carroll, Minority Staff Director; Chris Knauer, Minority Oversight Staff Director; Miles Lichtman, Minority Policy Analyst; C.J. Young, Minority Press Secretary; and Perry Lusk, Minority GAO Detailee.

* This is an edited, reformatted and augmented version of Hearing before the Subcommittee on Oversight and Investigations, of the Committee on Energy and Commerce, House of Representatives, One Hundred Fifteenth Congress, Second Session, Serial No. 115–140, dated June 15, 2018.

**OPENING STATEMENT OF HON. GREGG HARPER, A
REPRESENTATIVE IN CONGRESS FROM THE STATE OF MISSISSIPPI**

Mr. HARPER. Good morning. Today, the subcommittee continues its longstanding oversight of the U.S. public health system's preparedness to respond to biological threats and emerging infectious diseases that endanger the public health. The purpose of today's hearing is to hear from top public health experts on the good work being done at their agencies to protect the public and to explore where improvements need to be made.

The biological threats facing the United States in today's global society are varied, ever-evolving and, in some cases, intensifying. The CDC just reported that the seasonal influenza claimed the lives of 172 children during the most recent flu season, making it the deadliest seasonal flu season for children on record.

In recent years, the U.S. has also seen an increase in the number of antibiotic-resistant bacteria. Around the world, viruses are emerging, adapting and, in some cases, reemerging. Currently, there is an Ebola outbreak in West Africa and a Nipah virus outbreak in India that has killed at least 17.

In recent years, we have also seen humans in China contract the H7N9 strain of influenza which has been confined to birds. The H7N9 influenza strain is rated by the CDC's influenza risk assessment tool as posing the greatest risk to cause a public pandemic.

The 2013 ricin mailings addressed to President Obama and Senator Roger Wicker that originated in my home State of Mississippi, as well as the 2001 anthrax mailings and foreign terrorist threats, is a reminder of the risk of intentional biological attacks.

Today's hearing is especially timely, given that the committee is considering bipartisan legislation sponsored by Mrs. Brooks and Ms. Eshoo to reauthorize the Pandemic and All Hazards Preparedness Act, PAHPA, which is set to expire at the end of September. Passage of PAHPA's reauthorization would not only provide critical certainty for public health agencies and industry partners, it would also bring about some much needed reforms. One such reform proposed in the legislation is transferring control of the Strategic National Stockpile from the CDC to HHS' Office of the Assistant Secretary for Preparedness and Response, to improve management of the stockpile.

A year ago, HHS' Office of Inspector General reported systemic issues with security and inventory management of the stockpile, risking CDC's ability to deploy the stockpile during a public health emergency. These issues need to be addressed, as does improving the training of State and local stakeholders on deployment of medical countermeasures.

Administrative reforms are also of interest. For example, are there ways to improve the timeliness of the decisionmaking process on threat assessments and appropriate countermeasures? Effective threat detection has been a subject of committee oversight. In 2016, the committee questioned the CDC about the effectiveness of its Laboratory Response Network, or LRN, which is responsible for developing assays for public health labs to test for the presence of Federal select agents.

In a May 2017 letter to the committee, the CDC reported that the LRN had only developed three assays approved by the FDA to detect specific Federal select agents. While the LRN has also had those cleared by the FDA under emergency use authorization, after nearly 20 years of this program, with about \$135 million in funding over the last decade,

could the LRN have cleared a significantly higher number of assays through the most rigorous FDA 510(k) process?

Finally, maintaining public confidence in critical Federal biopreparedness research is essential. In response to safety lapses in 2014 and to an expert panel's recommendations, the CDC and FDA each formed new offices in 2015 to centralize and elevate oversight of laboratory safety, with the directors of those offices reporting directly to the agency head.

These changes sent a strong message that lab safety was a top priority, backed by the clout of direct backing from the agency head. Unfortunately, both agencies seem to be backtracking from this good direction.

In the FDA's case, less than a year after this administration approved the direct report organization—or reorganization, the sudden change is curious and would seem to be a step in the wrong direction. So we need to hear more details about the basis for this new direction.

I would like to thank the distinguished members of our panel for being here today and for your service to our country.

I now recognize the ranking member of the subcommittee from Colorado, Ms. DeGette, for 5 minutes.

[The prepared statement of Mr. Harper follows:]

PREPARED STATEMENT OF HON. GREGG HARPER

Good morning, today the Subcommittee continues its long-standing oversight of the U.S. public health system's preparedness to respond to biological threats and emerging infectious diseases that endanger the public health. The purpose of today's hearing is to hear from top public health experts on the good work being done at their agencies to protect the public, and to explore where improvements in biopreparedness may still be needed.

The biological threats facing the United States in today's global society are varied, ever-evolving, and in some cases, intensifying. The CDC just reported that the seasonal influenza claimed the lives of 172 children during the most recent flu season, making it the deadliest seasonal flu season for children on record. In recent years the U.S. has also seen an increase in the number of antibiotic resistant bacteria.

Around the world, viruses are emerging, adapting, and in some cases, re-emerging. Currently, there is an Ebola outbreak in West Africa and a Nipah (*pronounced Knee – Pah*) virus outbreak in India, that has killed at least 17 people.

In recent years, we have also seen humans in China contract the H7N9 strain of influenza, which had been confined to birds. The H7N9 influenza strain is rated by the CDC's Influenza Risk Assessment Tool as posing the greatest risk to cause a possible pandemic.

The 2013 ricin mailings addressed to President Obama and Senator Roger Wicker that originated in my home state of Mississippi, as well as the 2001 anthrax mailings and foreign terrorist threats, is a reminder of the risk of intentional biological attacks.

Today's hearing is especially timely given that the Committee is considering bipartisan legislation, sponsored by Ms. Brooks and Ms. Eshoo, to reauthorize the Pandemic and All-Hazards Preparedness Act (PAHPA), which is set to expire at the end of September. Passage of PAHPA's (*pronounced Pah – Pah*) reauthorization would not only provide critical

certainty for public health agencies and industry partners, it would also bring about some much-needed reforms.

One such reform, proposed in the legislation, is transferring control of the Strategic National Stockpile from the CDC to HHS' Office of the Assistant Secretary for Preparedness and Response to improve management of the Stockpile. A year ago, HHS's Office of Inspector General reported systemic issues with security and inventory management of the Stockpile, risking CDC's ability to deploy the stockpile during a public health emergency. These issues need to be addressed, as does improving the training of state and local stakeholders on deployment of medical countermeasures.

Administrative reforms are also of interest. For example, are there ways to improve the timeliness of the decision-making process on threat assessments and appropriate countermeasures?

Effective threat detection has been a subject of Committee oversight. In 2016, the Committee questioned the CDC about the effectiveness of its Laboratory Response Network (LRN), or LRN, which is responsible for developing assays for public health labs to test for the presence of federal select agents. In a May 2017 letter to the Committee, the CDC reported that the LRN had only developed three assays approved by FDA to detect specific federal select agents. While the LRN has also had assays cleared by the FDA under Emergency Use Authorization, after nearly 20 years of this program with about \$135 million in funding over the last decade, could the LRN have cleared a significantly higher number of assays through the more rigorous FDA 510(k) process?

Finally, maintaining public confidence in critical federal biopreparedness research is essential. In response to safety lapses in 2014 and to an expert panel's recommendations, the CDC and FDA each formed new offices in 2015 to centralize and elevate oversight of laboratory safety, with the directors of those offices reporting directly to the agency head. These changes sent a strong message that lab safety was a top priority backed by the clout of direct backing from the agency head. Unfortunately, both agencies seem to be backtracking from this good direction, in the FDA's case less than a year after this Administration approved the direct-report reorganization. The sudden change is curious, and would seem to be a step in the wrong direction. We need to hear more details about the basis for this new direction.

I would like to thank the distinguished members of our panel for being here today and for your service to our country. I now recognize the Ranking Member of the Subcommittee from Colorado, Ms. DeGette, for five minutes.

OPENING STATEMENT OF HON. DIANA DEGETTE, A REPRESENTATIVE IN CONGRESS FROM THE STATE OF COLORADO

Ms. DEGETTE. Thank you, Mr. Chairman.

I know we agree that preparing this country for a bioincident is of critical importance. The threat, as you said, is real and it's growing.

In April, the CDC reported that in 2017, Colorado saw 25 cases of an antibiotic-resistant bacteria known descriptively as the nightmare bacteria, because 50 percent of those infected by it die. Thankfully, those cases were isolated, but the same CDC study noted that it's

possible for these germs to “spread like wildfire.” If that happens, we need to know that we’re able to respond.

We’ve looked at this issue in this subcommittee many times over the years, as our panel well knows. It’s a regular appearance, and I want to thank you for coming again. And again and again, we’ve found that the Federal Government has to scramble to address biosafety incidents.

Those of us who were here during the fall of 2001 vividly recall the chaos that a few small envelopes of anthrax caused on Capitol Hill. Offices were closed. Buildings were fumigated. Some congressional business was suspended, and thousands of staffers and other personnel lined up for days to get tested for exposure. Far worse, some of the workers in our Postal Service were infected and died.

In 2009, we again had to scramble to produce sufficient doses of the H1N1 swine flu vaccine to protect against this new strain of the disease.

In 2014, hospitals and healthcare providers were not adequately prepared to deal with the arrival of Ebola patients in America. In one case, a hospital in Dallas failed to diagnose Ebola in a patient who had traveled to West Africa and discharged him. The virus was later transmitted from that patient to two healthcare workers. In the days and weeks that followed, important questions were raised about how this event was handled and were we adequately prepared for the larger event.

And then, of course, in 2015, the Zika outbreak underscored the need for the U.S. Government to focus on disease preparedness every day. And I know our panel here today does just that.

I’d like to know today, though, what lessons we’ve learned from these incidents, and I want to know how the agencies are using what we’ve learned to better prepare for the next crisis, because there will be one.

For example, do we have adequate medical countermeasures in place to respond quickly when an outbreak occurs or a toxin is released? Do we have the capacity to quickly deliver these counter-measures to the doctors and nurses who will actually use them? And do the healthcare workers understand how to deploy the countermeasures?

Similarly, research into emerging pathogens and existing pathogens that have mutated is key to helping us quickly respond to new and expanding outbreaks. How is this research informing our surveillance and detection methodologies? Are we prioritizing research into threats of greatest concern? And are we dedicating adequate resources to the threats?

I also want to hear more about how all of our agencies—CDC, ASPR, NIAID and FDA—coordinate their research, surveillance, and response efforts. Because while each one of these agencies today has a specific valuable role to play in ensuring preparedness, nobody can operate effectively alone.

In fact, one major finding of the Blue Ribbon Panel’s 2015 report on biodefense preparedness was these agencies must ensure they’re equipped to work together to respond to pandemics. The Blue Ribbon report also found that the Federal Government must dramatically increase the support provided to local jurisdictions to help them build and sustain their biodefense capabilities.

Local providers like hospitals and healthcare workers will be on the front lines in a public health emergency. I want to ensure that we’re adequately supporting these providers, as well as State and local Health Departments, so they are equipped to detect incidents when they happen and respond appropriately.

Mr. Chairman, I'm really hoping we'll hear today that we've made tangible, measurable progress in this area, but, again, I urge us to revisit the work of the Blue Ribbon Panel and some of its findings to determine what more we need to do to better prepare the Nation for the threats that we will be discussing today.

I just can't thank our panel today enough for the tireless work that they put in to keeping America safe. We always have a great opportunity to hear from you, and we know that you're working hard. We think by having you come up here and take the time, it really helps us represent our constituents, and it helps all of us be better prepared for the next emergency that faces us.

Thank you, and I yield back.

Mr. HARPER. The gentlewoman yields back.

The chair now recognizes the chairman of the full committee, the gentleman from Oregon, Mr. Walden, for 5 minutes.

OPENING STATEMENT OF HON. GREG WALDEN, A REPRESENTATIVE IN CONGRESS FROM THE STATE OF OREGON

Mr. WALDEN. Thank you very much, Mr. Chairman. To all our committee members, thanks for your work on this. And to our panelists, thank you, not only for your guidance on this issue, but also what we tap into you for along the way. And so we appreciate your professionalism and your assistance in our policy debates.

The topic of biopreparedness really hits home for me. I think I was the first Member of Congress to be diagnosed with H1N1 years ago. Not a distinction I was glad to get, but one apparently I had.

But more than that, 30 years ago, a religious group called the Rajneeshees moved to Oregon. You may have seen the documentary on Netflix called *Wild Country*. And if you read Judith Miller's book *Germs*, you'll find it was the largest bioterror attack in the Nation's history, but it took the Federal Government a year, I think she wrote, to admit that that's really what it was. They grew their own salmonella and then sprinkled it over salad bars in Dalles, Oregon, and sickened 751 people, many of whom I know.

Deliberate biological attacks are just one risk. With more global travel, there's, of course, increased risk of spread of infectious diseases. As we've seen with influenza, our vaccines must be constantly updated to keep up with the latest strains. Meanwhile, other pathogens can develop antibiotic resistance, and our ability to quickly recognize evolving diseases and respond to new outbreaks is reliant on the testing and treatment and capabilities in the men and women who do the work that you all oversee.

Lack of preparation is not an option. A mock pandemic exercise hosted last month by Johns Hopkins Center for Health Security with a group of current and former government officials, including our own colleague Susan Brooks, I'm told was quite eye-opening. The exercise resulted in a failure to develop a vaccine within 20 months, and that led in this exercise to 150 million deaths globally. So obviously, we've got to do more to be prepared for these types of outbreaks.

So that's where the reauthorization of the Pandemic and All Hazards Preparedness Act comes in. PAHPA originally was adopted in 2006. It's set to expire at the end of September. We intend to move forward with legislation prior to that.

Our Health Subcommittee met just last week to consider a bipartisan discussion draft to reauthorize this law and continues to fine-tune it. It's critically important Congress reauthorizes this law in time and to make sure that all levels of government are well-equipped to handle, not just current and emerging biothreats, but also chemical attacks, radiological emergencies, cybersecurity incidents, and mass casualty events.

Through letters, hearings, and investigations, the Committee has raised numerous issues regarding biological threats to the U.S. and our nation's ability to respond to infectious disease outbreaks. For example, the Committee has examined concerns about the CDC's management and the security of the Strategic National Stockpile and the capabilities of CDC Laboratory Response Network. The Trump administration is set to transfer management of the stock-pile from the CDC to the Assistant Secretary for Preparedness and Response, known as ASPR. And we look forward to hearing more details about how this transfer will work.

Another area of interest to the Committee is the improvement of our biosurveillance capabilities. Innovation in this field could bolster our public health response in the event of an attack or epidemic. So I'll be interested in learning more about that as well.

One thing we do know, the Federal Government needs to act faster to identify and determine material threats. The Department of Homeland Security in March 2018 made a material threat determination for pharmaceutical-based agents such as Fentanyl. It took 2 years for the DHS to make this designation, yet carfentanil, a highly potent form of Fentanyl, was used in a terrorist attack more than 15 years ago. So it's only after that designation is made that the Public Health Emergency Medical Countermeasures Enterprise can approve countermeasure development and acquisition. If we knew about it 15 years ago and it took 2 years to get that designation, we can do better.

Maintaining public support for critical biopreparedness research relies on Federal scientists and researchers working with these diseases and dangerous pathogens in a safe and secure manner. Following several safety lapses at CDC and FDA labs in 2014, both FDA and CDC created new offices to oversee and prioritize lab safety. These are positive steps. The recent proposals at these agencies to lower the status of their lab safety offices raises concerns with this committee.

So I thank you for being here today.

And I'd like to yield the balance of my time to Dr. Burgess and hopefully to Mrs. Brooks.

[The prepared statement of Chairman Walden follows:]

PREPARED STATEMENT OF HON. GREG WALDEN

Mr. Chairman, thank you for holding this hearing. The topic of biopreparedness hits home for me. Some of you may recall that in 2009 I was diagnosed with H1N1—the swine flu. It was reported at the time that I was the first Member of Congress to contract swine flu—a distinction I'm not particularly proud of. But that's not all. The first and single largest

bioterrorism attack in the U.S. occurred in my district. More than 30 years ago, a group of Rajneeshee cult members used salmonella to contaminate at least 10 restaurant salad bars in The Dalles, Oregon, causing at least 751 people to get ill.

Deliberate biological attacks are just one risk. With more global travel, there is increased risk of the spread of infectious diseases.

As we've seen with influenza, our vaccines must be constantly updated to keep up with the latest strain mutations. Meanwhile other pathogens can develop antibiotic resistance. Our ability to quickly recognize evolving diseases and respond to new outbreaks is reliant on our testing and treatment capabilities.

Lack of preparation is not an option. A mock pandemic exercise hosted last month by Johns Hopkins Center for Health Security with a group of current and former government officials, including our colleague Susan Brooks, was eye opening. This exercise resulted in a failure to develop a vaccine within 20 months and led to 150 million deaths globally. We must do more. We must be prepared for potential out-breaks.

That's where the reauthorization of the Pandemic and All-Hazards Preparedness Act (PAHPA) comes in. PAHPA, originally adopted in 2006, is set to expire at the end of September. Our Health Subcommittee met just last week to consider a bipartisan discussion draft to reauthorize this law and continues to fine tune it. It is critically important Congress reauthorizes this law to ensure that all levels of government are well-equipped to handle not just current and emerging biothreats, but also chemical attacks, radiological emergencies, cybersecurity incidents, and mass casualty events.

Through letters, hearings and investigations, the committee has raised numerous issues regarding biological threats to the U.S. and our nation's ability to respond to infectious disease outbreaks. For example, the committee has examined concerns about the CDC's management and security of the Strategic National Stockpile, and the capabilities of the CDC Laboratory Response Network. The Trump Administration is set to transfer management of the stockpile from the CDC to the Assistant Secretary for Preparedness and Response (ASPR), and we look forward to hearing more details about how this transfer will work.

Another area of interest to the committee is the improvement of our biosurveillance capabilities. Innovation in this field could bolster our public health response in the event of an attack or epidemic. I will be interested to learn whether more intensive research could help expedite addressing the technical challenges.

One thing we do know: The Federal Government needs to act faster to identify and determine material threats. The Department of Homeland Security (DHS) in March 2018 made a material threat determination for pharmaceutical-based agents such as fentanyl. It took 2 years for DHS to make this designation. Yet carfentanil, a highly potent form of fentanyl, was used in a terrorist attack more than 15 years ago. It's only after that designation is made that the Public Health Emergency Medical Countermeasures Enterprise can approve countermeasure development and acquisition. We must move faster.

Maintaining public support for critical biopreparedness research relies on federal scientists and researchers working with these diseases and dangerous pathogens in a safe and secure manner. Following several safety lapses at CDC and FDA labs in 2014, both CDC and FDA created new offices to oversee and prioritize lab safety. These were positive steps, but recent proposals at these agencies to lower the status of their lab safety offices raise concerns.

I'd like to thank our witnesses for being here with us today. We value the feedback and insight you provide and look forward to today's discussion.

* * *

Mr. BURGESS. Thank you, Mr. Chairman.

And this issue is one that is important and timely for this sub-committee. And last week, the Health Subcommittee had a hearing on the discussion draft of the Pandemic and All Hazards Preparedness Act authored by Representatives Brooks and Eshoo. At that hearing, we heard from witnesses with firsthand experience in combating these biological threats to our nation and received input on the draft legislation.

Certainly, our witness panel today is well-known to us and they are all experts. I look forward to hearing from our witnesses.

And I thank you, Mr. Chairman, and I will yield to Mrs. Brooks.

Mr. HARPER. Maybe with unanimous consent, due to your leadership role in this, 30 seconds.

Mrs. BROOKS. Thank you, Mr. Chairman.

And thank you to our witnesses for your work on this public health and national security issue.

Last February, our subcommittee here held a hearing examining how we best combat biological threats. And I'm pleased we're once again examining the state of our preparedness as we prepare to reauthorize PAHPA.

As everyone here knows, it is not a question of if we face a threat; it's a question of again, once again, when we face a threat. And we've been reminded by the stories that we've heard here today that these types of incidents have already happened in our country over the last decade and a half.

Created in 1999, the National Stockpile is the repository of vaccines, antibiotics, and supplies used in the event of an attack or an outbreak. But HHS OIG, in June of 2017, issued a report identifying serious systemic issues within the CDC's management of the stockpile.

I look forward to hearing from our witnesses today how we are going to ensure that our stockpile is properly managed and that we can be prepared as a country for whatever threat we are and may face.

I yield back.

Mr. HARPER. The chair now recognizes the ranking member of the full committee, the gentleman from New Jersey, Mr. Pallone, for 5 minutes.

OPENING STATEMENT OF HON. FRANK PALLONE, JR., A REPRESENTATIVE IN CONGRESS FROM THE STATE OF NEW JERSEY

Mr. PALLONE. Thank you, Mr. Chairman.

Ensuring that our nation is equipped to respond to pandemics, natural disasters, and the accidental or intentional release of toxins is a key part of protecting public health. Past work by this committee has suggested that our nation has not always been as prepared as we need

to be, so I'm glad that we're having this hearing today, and I hope to hear that we have made tangible progress towards increasing our Nation's preparedness.

In 2015, the Blue Ribbon Panel on Biodefense conducted a comprehensive review of the Federal Government's biopreparedness efforts. The panel found that, "The Nation is dangerously vulnerable to a biological event." It produced an extensive report recommending 30 action items for our public health infrastructure to address.

While the Blue Ribbon Panel was the most recent high-level commission to examine our nation's biopreparedness, it was not the first. In fact, for many years, experts have warned that our ability to respond to biologic and other emerging threats must be improved.

These recommendations remain important today, because the emerging health threats this country faces continue to grow. Just this week, officials announced that a child in Idaho had contracted bubonic plague. Last year, an outbreak of this plague killed 200 people in Madagascar.

In March, we heard at a hearing that the threat of pandemic flu is among the greatest concerns in the public health world. And antibiotic resistance also poses a major threat to public health, killing 23,000 Americans every year and making everyday procedures like surgery and chemotherapy increasingly risky. In May, a study showed that warming temperatures were associated with higher levels of antibiotic resistance in common strains of bacteria.

Extreme weather events can also lead to serious public health emergencies. The hurricanes in Puerto Rico, the Virgin Islands, Texas, and Florida last year were a stark reminder of this fact. We must be prepared to address threats from all these sources.

The Blue Ribbon Panel produced many recommendations for improving our biopreparedness, and I hope our witnesses will show that we have made real progress. For example, I hope to hear that the agencies have established a plan for who will take the lead in response to a public health threat and how the efforts will be coordinated.

Along these same lines, I hope we will learn how CDC, NIH, ASPR, and FDA are working together to identify the greatest threats and to prioritize the research, surveillance, and response capabilities needed to target these threats.

We must also focus on how these agencies collaborate with State and local health departments as well as healthcare providers, such as hospitals. These entities are likely to be the first to see patients impacted by an infectious disease outbreak or other incident. In most cases, they'll be the ones to dispense countermeasures and to treat those impacted.

In 2014, for example, we witnessed the negative consequences that ensued when our healthcare infrastructure was unprepared to diagnose and treat patients with Ebola. A hospital failed to detect the disease in the patient in Dallas, and that patient later transmitted Ebola to two healthcare workers. This incident led to a serious question about whether we would be able to handle a larger scale event or incident. And we must make sure everyone on the ground has all the resources they need to respond effectively in such a crisis.

We also want to hear more about how we are conducting surveillance so that when an outbreak happens or a toxin is released, we know as soon as possible. While we cannot anticipate every possible new or mutated pathogen, if we can quickly detect when such a pathogen has emerged, we can respond much more effectively.

And along these same lines, I understand the CDC is gathering a substantial amount of data from laboratories, public health departments, and clinicians across the country every day. So we must ensure that this agency has the resources it needs to effectively use and analyze this data as it comes in.

And finally, I want to hear more about what we're doing to prioritize development of medical countermeasures to help us respond to a biosafety incident. Countermeasures include preventative measures like vaccines as well as therapeutics like antibiotics and antivirals.

BARDA, I understand that you work closely with the private sector to develop many of these products, and I hope that we will hear today about how these partnerships have produced useful, safe, and effective products that truly address the challenges we face.

So, Mr. Chairman, I'd like to thank our panel once again for being here. Preparing for these threats is certainly not easy, but I'm confident that you're up for the task as long as we do our part and provide you with all the resources that you need.

I yield back, Mr. Chairman.

Mr. HARPER. The gentleman yields back.

I ask unanimous consent that the members' written opening statements be made part of the record. Without objection, they will be so entered into the record.

And additionally, I ask unanimous consent that Energy and Commerce members not on the Subcommittee on Oversight and Investigations be permitted to participate in today's hearing. Without objection, so ordered.

I would now like to introduce our witnesses for today's hearing. First, we have Dr. Rick Bright, Director of Biomedical Advanced Research and Development Authority and Deputy Assistant Secretary at the Office of the Assistant Secretary for Preparedness and Response. Next is Dr. Anne Schuchat, Principal Deputy Director at the Centers for Disease Control and Prevention. Then we have Dr. Anthony Fauci, Director of the National Institute of Allergy and Infectious Diseases at the National Institutes of Health. Finally, we have Rear Admiral Denise Hinton, Chief Scientist at the U.S. Food and Drug Administration.

We welcome all of you.

And you are each aware that the Committee is holding an investigative hearing and when doing so has had the practice of taking testimony under oath. Do you have any objection to testifying under oath?

Let the record reflect that all of the witnesses have reflected that they do not.

The chair then advises you that under the rules of the House and the rules of the committee, you're entitled to be accompanied by counsel. Do you desire to be accompanied by counsel during your testimony today?

Let the record reflect that each of the witnesses reflected that they do not.

In that case, if you would please rise and raise your right hand, I will swear you in.

[Witnesses sworn.]

Mr. HARPER. You are now under oath and subject to the penalties set forth in title 18, section 1001 of the United States Code. You may now give a 5-minute summary of your written statement.

And I will begin with you, Dr. Bright. Welcome back.

Testimony of Rick A Bright, Ph.D.

Mr. BRIGHT. Thank you.

Chairman Harper, Ranking Member DeGette, and distinguished members of the subcommittee, it's a pleasure to speak today on behalf of our Assistant Secretary for Preparedness Response to discuss the state of the Nation's health security preparedness.

I'm Dr. Rick Bright, the Director of the Biomedical Advanced Research and Development Authority, BARDA, and the Deputy Assistant Secretary for Preparedness and Response.

ASPR's mission is to save lives and protect Americans from 21st century health security threats. BARDA is a component of ASPR created to ensure that we have products to protect people from numerous dire threats that we face as a nation. ASPR's staff is dedicated to preparing for and responding to these threats.

We are currently coordinating HHS' response to the Ebola outbreak in the DRC and monitoring H7N9 influenza in China. In communities affected by last year's hurricanes, we're there for the long haul, helping local health officials manage recovery and build resilience.

ASPR coordinates across the Federal Government to support State and local partners in emergencies. We enhance medical search capacity through our National Disaster Medical System and Hospital Preparedness Program, and we oversee the development and procurement of medical countermeasures. We've made great progress in public health preparedness response since Congress established ASPR and BARDA in 2006.

BARDA was created to bridge government and industry to accelerate the development of life-saving medical countermeasures that would not otherwise be available. We use flexible authorities, multiyear advanced funding, public-private partnerships, and deep technical expertise to push vaccines, drugs, and diagnostics towards FDA approval. In our 12 years, BARDA has formed over 200 public-private partnerships with industry to accomplish our mission.

I want to pause for one second to acknowledge the hard work of our partners who, together with the U.S. Government, work very hard to create a more secure nation with not only products but capabilities to respond when needed. These partnerships have led to 35 FDA approvals of products that form a protective shield for our nation against a range of the most serious CBRN and pandemic and emerging infectious disease threats.

Through Project BioShield, BARDA has supported 27 vaccines, drugs, and devices to address national security threats, including smallpox, anthrax, botulinum, rad/nuc and chemical exposure. Fourteen of these are now in the Strategic National Stockpile for use in an emergency, and seven have now achieved FDA approval. These outcomes are the spirit of PAHPA: leadership, coordination, partnerships, and capabilities, working together to protect our nation.

While this effort has created life-saving products to be procured by the SNS, it has also created challenges to acquire and sustain sufficient quantities to address the requirements needed for each threat. Critically, each product also represents a company with a response capability that must be sustained to ensure we have these products available when they're needed. Project BioShield and the SNS together represent a marketplace for these products that would otherwise never exist and the products would quickly vanish without it.

PAHPA, ASPR, BARDA, and BioShield have all played valuable roles in enhancing our preparedness. However, the threats continue to evolve, and technology to modify and create new deadly threats have become simpler. We must modernize our capabilities, emphasizing an end-to-end approach, ranging from early detection through the last mile of administering vaccines and treatments to patients.

With new technologies and innovation, the time is here to apply transformative approaches to these daunting health security problems. Last week, we announced a new initiative called DRIVE, a nationwide business-friendly approach to identify, capture, and accelerate life-saving innovation. Using authorities you enacted in the 21st Century Cures Act, DRIVE brings together innovators, government, and now the investment community to create solutions for today's threats.

As you consider reauthorization of PAHPA, important changes to BARDA's authorities would sustain and enhance our capabilities. First, advanced appropriations for Project BioShield will attract more partners to support our mission. Without this consistent and guaranteed market, the companies are reluctant to work with us. Second, an authorization of appropriation for BARDA's pandemic influenza program will sustain our domestic flu vaccine production capabilities, modernize our vaccine technologies, and bring new treatments and faster diagnostics into the homes across America.

I look forward to working with members of this panel, this subcommittee, your congressional colleagues, and I'm grateful for the opportunity to present to you today and look forward to your questions.

[The prepared statement of Mr. Bright follows:]

**WRITTEN TESTIMONY, HOUSE COMMITTEE ON ENERGY AND
COMMERCE, SUBCOMMITTEE ON OVERSIGHT AND INVESTIGATIONS,
THE STATE OF U.S. PUBLIC BIOPREPAREDNESS: RESPONDING TO
BIOLOGICAL ATTACKS, PANDEMICS, AND EMERGING INFECTIOUS
DISEASE OUTBREAKS**

Statement of Rick Bright, Ph.D.

Director, Biomedical Advanced Research and Development Authority

Deputy Assistant Secretary for Preparedness and Response

For Release on Delivery Expected at

9:00 am

June 15, 2018

Good morning Chairman Harper, Ranking Member DeGette, and other distinguished Members of the Subcommittee. I am Dr. Rick Bright, the Director of the Biomedical Advanced Research and Development Authority (BARDA) and the Deputy Assistant Secretary for Preparedness and Response (ASPR) at the Department of Health and Human Services (HHS). Thank you for the opportunity to testify before you today on behalf of ASPR to discuss the state of our nation's preparedness for 21st century health security threats, including biological incidents, as the Energy and Commerce Committee prepares to consider the second reauthorization of the Pandemic and All-Hazards Preparedness Act (PAHPA).

My expertise is in developing drugs, vaccines, diagnostics and other medical countermeasures (MCMs) for health security threats. In this testimony, I will cover a broader range of ASPR programs and activities, including some background on the nature of the health security threats facing the United States, the mission and duties of ASPR and BARDA, and our vision for where these areas can be strengthened.

**Readiness for 21st Century Health Security Threats:
A National Security Imperative**

One of the federal government's fundamental responsibilities is to provide for the common defense - to protect the American people, our homeland, and our way of life. The strength of our nation's public health and medical infrastructure, and the capabilities necessary to quickly mobilize a coordinated national response to emergencies and disasters, are foundational for the quality of life of our citizens and vital to our national security. The health security threats facing the United States during the 21st century are increasingly complex and dangerous. Therefore, improving national readiness and response capabilities for 21st century health security threats is a national security imperative.

Additionally, we have witnessed the impacts of naturally occurring outbreaks such as pandemic influenza, outbreaks of Ebola and SARS, and the emergence of antibiotic resistant bacteria. ASPR is currently engaged in coordinating HHS's response to the Ebola outbreak in the Democratic Republic of Congo and monitoring other potential emerging infectious

diseases that could cause a pandemic, such as the H7N9 influenza strain circulating in China. This year marks the 100-year anniversary of the 1918 influenza pandemic, which killed more people than World War I. During that pandemic, more than 25 percent of the U.S. population became sick and 675,000 Americans, many of them young, healthy adults, died from the highly virulent influenza virus. As our healthcare delivery systems become more networked, cyber-attacks like the 2017 WannaCry incident that affected approximately 150 countries remind us that technological advancements have trade-offs in the form of new vulnerabilities and risks. Finally, we face extreme weather events, such as the recent 2017 hurricane season in which Hurricanes Harvey, Irma, and Maria caused an unprecedented amount of damage and destruction, reminding us of the awesome destructive power of nature and our vulnerability.

These are threats that most people would rather not think about. However, when natural disasters, disease outbreaks, or attacks occur, the people expect our federal government to be ready to quickly respond to save lives and decrease morbidity. Since September 11, 2001, the nation has made great progress in building our response capabilities to protect America from health security threats; however, we still have much to do.

Assistant Secretary for Preparedness and Response: Mission and Duties

ASPR's mission is to save lives and protect Americans from 21st century health security threats. On behalf of the Secretary of HHS, ASPR leads public health and medical preparedness for, response to, and recovery from, disasters and public health emergencies, in accordance with the National Response Framework (NRF) (Emergency Support Function (ESF) No. 8, Public Health and Medical Services), as well as the National Disaster Recovery Framework (Health and Social Services Recovery Support Function). ASPR also supports HHS's role in the delivery of mass care and human services in emergencies (NRF ESF No. 6, Mass Care, Emergency Assistance, Temporary Housing, and Human Services).

When ASPR was established by Congress a decade ago in PAHPA, the law's objective was to create "unity of command" by consolidating Federal nonmilitary public health and medical preparedness and response functions under the ASPR. This approach was modeled on the Goldwater-Nichols Act that created the Department of Defense (DoD) combatant commands; the impetus was the disorganized and fragmented response to Hurricane Katrina in 2005.

ASPR coordinates across HHS and the Federal interagency to support state, local, territorial, and tribal health partners in preparing for, responding to, and recovering from, emergencies and disasters. In partnership with HHS agencies, ASPR works to enhance U.S. medical surge capacity by organizing, training, equipping, and deploying HHS public health and medical personnel, such as National Disaster Medical System (NDMS) teams, and providing logistical support for HHS personnel responding to public health emergencies. ASPR supports readiness at the state and local level by coordinating federal grants and cooperative agreements, such as the Hospital Preparedness Program (HPP), by programs like the Medical Reserve Corps (MRC), and carrying out drills and operational exercises. ASPR also oversees advanced research, development, and procurement of medical countermeasures (e.g., vaccines, medicines, diagnostics, and other necessary medical supplies), and

coordinates the stockpiling of such countermeasures. As such, ASPR manages BARDA, Project BioShield, and the Public Health Emergency Medical Countermeasures Enterprise.

ASPR Priorities for Improving Preparedness, Response, and Recovery

HHS and ASPR have made significant progress since PAHPA was enacted in 2006 and was reauthorized in 2013. However, we still have work to do to ensure we are ready to save lives and protect Americans. ASPR has four key priorities for building the necessary readiness and response capabilities for 21st century health security threats:

First, provide strong leadership, including clear policy direction, improved health security threat awareness, and secure adequate resources.

Second, seek the creation of a “regional disaster health response system” by better leveraging and enhancing existing programs – such as HPP and NDMS – to create a more coherent, comprehensive, and capable regional medical emergency response system integrated into daily care delivery.

Third, advocate for the sustainment of robust and reliable public health security capabilities. For ASPR to accomplish its mission, the Centers for Disease Control and Prevention (CDC) and other partners need support to quickly detect and diagnose infectious diseases and other health security threats. This is critical to rapidly and effectively dispensing medical countermeasures in an emergency.

Fourth, advance an innovative medical countermeasures enterprise by capitalizing on new authorities provided in the 21st Century Cures Act and advances in biotechnology and science. We must develop and maintain a robust supply of safe and efficacious vaccines, medicines, equipment, and other materiel to respond to 21st century health security threats, as well as the flexible response capabilities needed to handle the unexpected.

Strong Leadership

In the area of strong leadership, ASPR should continually evaluate and incorporate national health security threats by regularly coordinating with the Director of National Intelligence, the Department of Justice, and the Department of Homeland Security to assess current and future national health security threats.

Medical Countermeasures Enterprise

Congress established BARDA to speed up the availability and use of medical countermeasures (MCMs) by bridging the so-called “valley of death” in late stage development where many countermeasures for health security threats historically languished or failed. By using flexible, nimble authorities, multiyear advanced funding, strong public-private partnerships, and cutting edge expertise, BARDA has successfully pushed innovative MCMs, such as vaccines, drugs, and diagnostics, through advanced development to stockpiling and commercial availability with FDA approval or licensure.

In the last decade, BARDA’s strong partnerships with biotechnology and pharmaceutical companies, the National Institutes of Health, and other HHS components have led to 35 FDA approvals for 31 unique MCMs addressing chemical, biological, radiological, and nuclear

(CBRN) threats, pandemic influenza, and emerging and re-emerging infectious diseases. This is a staggering accomplishment in just 12 years.

BARDA has supported the development of 27 medical countermeasures against Department of Homeland Security (DHS)-identified national security threats through Project BioShield, including products for smallpox, anthrax, botulinum, radiologic/nuclear emergencies, and chemical events. Fourteen of these products have been placed in the Strategic National Stockpile and are ready to be used in an emergency and seven have achieved FDA approval. BARDA also has supported the development of 23 influenza vaccines, antiviral drugs, devices, and diagnostics to address the risk of pandemic influenza.

Because of these successes and progress, more medical countermeasures than ever before are eligible to be procured for the Strategic National Stockpile, thereby creating new challenges in terms of acquiring and maintaining sufficient quantities of medical countermeasures to address the requirements for identified health security threats.

Just last week, we announced an exciting new public-private engagement model – called DRiVE – which is designed to accelerate innovation, address some of the nation’s most pressing health security challenges, and potentially affect major healthcare markets.

At a time when synthetic biology and personalized medicine are not just conceivable but attainable, the time is right to apply an innovative approach to some of the most daunting, far-reaching health security problems, such as sepsis and early diagnosis of infectious diseases.

By implementing the authorities you provided to us in the 21st Century Cures Act, we are opening our doors to more innovators, and most importantly investors, to catalyze advances in science and technology.

ASPR has recommended important changes to BARDA’s authorization of appropriations to meet these challenges, including, most notably, additional advanced appropriations for Project BioShield, which would help incentivize private industry to dedicate resources to developing medical countermeasures to meet the government’s national security requirements. Without this “guaranteed market,” companies are reluctant to incur the costs required to focus development on MCMs for CBRN agents that would rely upon a limited government market that may not materialize when product development is complete. ASPR has also recommended adding a direct funding line for BARDA’s pandemic influenza preparedness activities. This authorization of appropriations will help sustain domestic influenza vaccine manufacturing capacity, as well as support better, faster influenza vaccine technologies and antivirals and rapid response platform technologies.

Regional Disaster Health Response System

The 2017 hurricane season highlighted the importance of regional healthcare readiness and medical surge capacity. ASPR led the public health and medical responses to Hurricanes Harvey, Irma, and Maria under the NRF Emergency Support Function No. 8 mission. ASPR worked closely with state and territory health officials in affected areas to augment care with NDMS teams, U.S. Public Health Service Commissioned Corps Officers, Department of Veterans Affairs personnel and facility support, and DoD transportation, facilities, naval vessels with medical and surgical capability, clinicians, and support personnel. Federal personnel under the supervision of HHS treated over 36,000 patients, and evacuated nearly 800 patients. HHS deployed over 4,500 personnel, awarded over 200 contracts, and provided nearly 950 tons of equipment. Today, HHS continues to support recovery efforts in impacted communities.

Despite our progress, each event teaches us that ASPR needs to improve its internal capabilities as well as enhance our support for the healthcare infrastructure across the country. As with MCM development, the nation's healthcare delivery infrastructure is mostly a private sector enterprise. We must better leverage and enhance existing federal programs – such as HPP and NDMS – to create a more coherent, comprehensive, and capable regional medical emergency response system integrated into daily care delivery. We call this the foundation of a “regional disaster health response system.”

NDMS was created during the Cold War to take care of military casualties from overseas conflicts in U.S. civilian hospitals. To modernize NDMS, strengthen capabilities, and ensure NDMS continues to provide critical support during and immediately after national public health and medical emergencies and national security special events, ASPR is implementing administrative changes and has recommended improvements to the NDMS statute to aid in ASPR's efforts to modernize this critical asset.

The Hospital Preparedness Program (HPP) was established after the September 11, 2001 terrorist attacks, with the goal of improving the capacity of local hospitals across the country to deal with disasters and a large influx of patients in an emergency. Using HPP funding, state grantees initially purchased equipment and supplies needed for emergency medical surge capacity. Over time, the program successfully evolved to support local coordinated healthcare coalitions, including hospitals, public health facilities, emergency management agencies, and emergency medical services providers. Fifteen years after it was established, HPP can be further strengthened to better utilize existing resources and enhance healthcare preparedness and response capabilities at the local level, and ASPR has recommended modifications to the HPP statute toward this end.

Conclusion

As Congress moves forward on the second reauthorization of PAHPA, we have the opportunity to build on the great progress made and further improve our national readiness and response capabilities for 21st century health security threats. On behalf of the HHS Assistant Secretary for Preparedness and Response, Dr. Bob Kadlec, I want to thank you, again, for your bipartisan commitment to this national security imperative, and we look forward to continuing to work together to enhance our nation's health security. I am happy to answer any questions you may have.

* * *

Mr. HARPER. Thank you, Dr. Bright.

The chair will now recognize Dr. Anne Schuchat for 5 minutes.

Welcome.

TESTIMONY OF ANNE SCHUCHAT, M.D.

Dr. SCHUCHAT. Thank you.

Chairman Harper, Ranking Member DeGette, and members of the subcommittee, thank you so much for the opportunity to testify before you today to describe CDC's role in preparing, detecting, and responding to biological attacks, pandemics, and emerging infectious disease outbreaks.

Today I'll highlight CDC's role in protecting the Nation against health threats. I'll describe our role in three areas: preparedness, detection, and response.

The three themes I'd like you to take away are, first, the work CDC does every day in public health lays the foundation for responding to emergencies. Second, the CDC's world-class scientific and medical expertise ensures we're ready to respond to any threat. And third, our longstanding connection to State and local health departments ensures that public health systems function effectively, both day-to-day and during emergency response.

Let me first address how we prepare for emergencies. CDC works every day with State and local health departments. In fact, we have 590 staff assigned to State and local health departments. We fund the Public Health Emergency Preparedness Cooperative Agreement Program and the Cities Readiness Initiative.

Public Health Emergency Preparedness grants go to every State, eight territories, and four cities. These funds support staff, enable exercises to test and validate capabilities, and pay for laboratory and communications equipment.

The Cities Readiness Initiative funds this nation's 72 largest cities, to develop and test plans to receive and dispense medical countermeasures from the Strategic National Stockpile.

CDC expertise helps assure protection of vulnerable populations against diverse threats. For example, CDC worked with the American Academy of Pediatrics, the FDA, and other stakeholders to address gaps in existing countermeasures for anthrax in children, taking advantage of the agency's scientific and clinical expertise and longstanding relationships with AAP.

Turning now to detecting threats. The CDC's lab and surveillance systems are able to detect and identify agents causing illness, ranging from infectious agents to chemical or radiation exposures. Every year, labs from all over the world send specimens to CDC, because they know we'll be able to identify pathogens that other laboratories cannot.

Rapid identification of disease permits intervention before a health threat becomes a crisis. CDC's Laboratory Response Network maintains an integrated, scalable, and flexible system of 125 Federal, State, and local laboratories. The development of this laboratory network established in 1999 has provided a larger capacity to test and report more quickly than was previously possible. For example, during the Zika virus outbreak response, CDC and our Laboratory Response laboratories processed over 207,000 specimens just for Zika.

Now I'll turn to response. When there's a crisis, CDC responds. We're able to rapidly deploy scientific and medical experts anywhere in the world. By the end of the 21-month Ebola response, 3,700 CDC staff had shifted from their day-to-day duties to assist with the response. 1,500 of our staff deployed to West Africa, making over 2,000 trips. Today, we're responding to a much smaller Ebola outbreak in the Democratic Republic of Congo.

During health emergencies, CDC communicates. For example, during the 2009 H1N1 response, CDC held 39 full press conferences and 21 telebriefings. During the Zika response, CDC published 51 morbidity and mortality weekly report articles to make sure the public health and healthcare professionals had the latest and best information.

Being able to prepare, detect, and respond to public health threats is a top priority for us at CDC. Our preparedness and response capabilities are built on broad and deep scientific,

medical, and program expertise. Our longstanding partnerships with State and local public health authorities ensures an integrated approach wherever that approach is needed, resulting in better responses and better public health outcomes, which translate to better protection of the people we serve.

Thank you, and I'll be happy to answer questions.

[The prepared statement of Dr. Schuchat follows:]

**WRITTEN TESTIMONY, HOUSE ENERGY AND COMMERCE
COMMITTEE, SUBCOMMITTEE ON OVERSIGHT AND INVESTIGATIONS:
THE STATE OF U.S. PUBLIC HEALTH BIOPREPAREDNESS:
RESPONDING TO BIOLOGICAL ATTACKS, PANDEMICS, AND
EMERGING INFECTIOUS DISEASE OUTBREAKS**

Statement of RADM Anne Schuchat, M.D.
Principal Deputy Director,
Centers for Disease Control and Prevention
Department of Health and Human Services

For Release upon Delivery
Expected at 9 a.m.
June 15, 2018

Chairman Harper, Ranking Member DeGette, and other members of the subcommittee. I am Rear Admiral Anne Schuchat, Principal Deputy Director of the Centers for Disease Control and Prevention (CDC). I appreciate the opportunity to be here today to discuss CDC's biopreparedness mission.

CDC is the eyes and ears of the biopreparedness complex, advancing the health security of the nation by helping communities prepare for, detect, and respond to, public health consequences of all hazards. These hazards include chemical, biological, radiological, and nuclear (CBRN) threats, natural disasters, and emerging (and re-emerging) infectious disease. For 72 years, this has been CDC's core mission.

CDC draws on expertise from across the agency, including world-class laboratory testing, public health surveillance (for disease detection), epidemiology, guidance to healthcare providers, incident management, logistics, emergency risk communication, disease control programs, distribution of medical countermeasures, human and animal medicine, and responder health and well-being. Our multidisciplinary workforce and integrated national and international systems broaden our capacity to detect and respond to any developing situation that could affect the health of people in the United States. This ability is enhanced by our long-standing relationships and close collaboration with federal, state, territorial, tribal, local, and global partners.

Prepare

The CDC's Public Health Emergency Preparedness Cooperative Agreement Program (PHEP) (which includes the Cities Readiness Initiative (CRI)) is central to CDC's programs to prepare communities across the nation for the next public health emergency. Additionally, CDC's role in the Public Health Emergency Medical Countermeasures Enterprise (PHEMCE) is critical to national preparedness for chemical, biological, radiological, nuclear threats, and emerging infectious diseases.

Public Health Emergency Preparedness Cooperative Agreement Program

The PHEP cooperative agreement program is the largest CDC state program and provided approximately \$600 million to state, local and territorial public health departments in FY 2017. The program supports these jurisdictions to develop plans for public health preparedness and response, and has been instrumental in integrating state and local health departments into their jurisdictions' emergency response structures. PHEP currently supports 62 awardees – the 50 states, eight territories and freely associated states, and four directly funded cities (New York City; Washington, D.C.; Chicago; and Los Angeles). Funding is awarded according to a base-plus population formula prescribed by statute, which ensures a minimum amount of funding to each awardee. These funds support preparedness and response staff, enable exercises to test and validate capabilities, provide training, and pay for laboratory and communications equipment essential to maintaining preparedness. In addition, CDC personnel support PHEP awardees by helping to identify and address gaps in preparedness capabilities, providing planning resources to ensure the needs of vulnerable populations are incorporated into response strategies, and improving response capabilities from experience gleaned during public health responses.

Cities Readiness Initiative (CRI)

CRI, funded through the PHEP cooperative agreement, enhances preparedness in the nation's 72 largest population centers, where nearly 60% of the U.S. population resides. These cities use CRI funds to develop, test, and maintain, plans to quickly receive medical countermeasures (MCMs) from the Strategic National Stockpile (SNS) and distribute them to local communities. This program, which relies on local boots on the ground, enables effective response to large-scale public health emergencies that require life-saving medications and medical supplies.

Public Health Emergency Medical Countermeasures Enterprise (PHEMCE)

Through participation in the ASPR-led Public Health Emergency Medical Countermeasures Enterprise (PHEMCE), CDC works with other HHS agencies and other federal partners to enhance preparedness for chemical, biological, radiological and nuclear threats, and emerging infectious disease. CDC brings together its scientific expertise and its experience in public health practice to inform the use of preventative measures and treatment during a public health emergency. Specifically, CDC subject matter experts from various CDC centers:

- Develop clinical guidance on the use of PHEMCE medical countermeasures – crucial to ensure health departments and clinicians know the safest, most effective way to use medical countermeasures.
- Inform operational details for SNS deployment – this includes informing which products should be deployed first based on epidemiology and laboratory data and clinical guidance.
- Provide technical expertise to state and local partners for the development and execution of deployment and dispensing plans for PHEMCE medical countermeasures.
- Conduct regular operational readiness reviews and exercises with state and local partners to prepare them and build their capacity to receive and dispense PHEMCE medical countermeasures. (In FY 2017, CDC supported 12 full-scale and tabletop exercises, and trained 3,758 Federal, state, territorial, and local emergency responders representing 13 different jurisdictions, on how to receive and distribute products from the Strategic National Stockpile).
- Provide regulatory science expertise to inform legal mechanisms (Emergency Use Authorizations, Emergency Use Instructions, and Investigational New Drug Protocols) and guidance on the use of MCM that have not received FDA approval or the use of FDA approved MCMs for – indications other than those included in FDA approval.

Protecting Vulnerable Populations during Emergencies

CDC has expertise and programs to promote effective support and care prior to, during, and after a public health emergency, for a wide variety of vulnerable populations. CDC's PHEP program requires states to develop emergency plans covering children, pregnant women, and other vulnerable populations such, as those isolated due to geography and individuals with disabilities. Subject matter experts within CDC's Children's Preparedness Unit champion the needs of children in public health emergencies and have supported 10 responses over the past 10 years. CDC also provides guidance to state and local health departments for dosage and administration of certain MCMs to certain populations. The Children's Preparedness Unit has recently completed a draft implementation plan for the pediatric use of Anthrax Vaccine Adsorbed (AVA) in the case of a large-scale event. AVA is the only FDA-licensed human anthrax vaccine in the U.S., but it is not currently approved for use in children. This implementation plan provides critical activities to ensure that programs are prepared to, and have the resources for, the efficient and safe administration of the vaccine to children.

Federal Select Agent Program

The nearly 300 entities in the U.S. that engage in laboratory research on biological select agents and toxins are regulated under the Federal Select Agent Program (FSAP), which is jointly managed by CDC and the Animal and Plant Health Inspection Service (USDA) to regulate the possession, use, and transfer of biological pathogens and toxins (e.g., anthrax, bubonic plague, smallpox, and ricin) that have the potential to pose a severe threat to human, animal, and/or plant health. The program aims to ensure that work with these dangerous

agents is conducted in as safe and secure manner as possible, and that they are stored and transported safely and securely.

Detect

World-class scientific expertise in disease progression, epidemiology, and laboratory methods ensures CDC is ready and able to detect and develop a response to a broad range of threats, including highly hazardous and infectious diseases like Ebola, smallpox, Zika, anthrax, and H7N9 influenza.

CDC uses advanced molecular detection techniques that combine next-generation genomic sequencing, high-performance computing, and epidemiology to identify pathogens faster and more accurately. Laboratories from all over the world send specimens to CDC because they know CDC will be able to identify pathogens that other laboratories cannot.

Through Advanced Molecular Detection investments, CDC is able to detect outbreaks faster, before they have become widespread. These advances are applied in dozens of areas such as foodborne disease, influenza, antimicrobial resistance, hepatitis, pneumonia, and meningitis. Moreover, CDC shares genetic sequencing capabilities with state and local health departments, and funds them to acquire these tools that help them respond more quickly and effectively at the local level, lessening the chances that disease outbreaks will spread.

CDC also maintains unique laboratory capability to rapidly detect exposure to radionuclides and more than 150 chemical threat agents. This information about human exposure helps public health officials rapidly assess health risk, determine the most effective treatment, and reduce additional exposures.

A Strong Laboratory Response Network

Rapid identification of disease is critical to addressing public health threats before they become a crisis. This requires that high quality specialized laboratory testing be available around the country. CDC's Laboratory Response Network is an integrated system of federal, state, and local laboratories that provides early detection and characterization of biological, chemical and other public health threats. The linking of laboratories and close partnership between laboratorians, epidemiologists and clinicians at CDC, state and local health departments, and healthcare facilities ensures the most rapid detection and mitigation of health threats.

For example, in response to the MERS (Middle East Respiratory Syndrome), Ebola and Zika virus outbreaks, CDC provided Laboratory Response Network laboratories across the United States with assays authorized for Emergency Use to quickly identify cases of infection during these outbreaks.

Another important laboratory network, begun in 2016, is CDC's Antibiotic Resistance Laboratory Network, which supports nationwide laboratory capacity to rapidly detect antibiotic resistance in healthcare, food, and community settings, and inform local responses to prevent the spread of antibiotic resistant bacteria, and protect people. The Antibiotic Resistance Laboratory Network includes seven regional laboratories, the National Tuberculosis Molecular Surveillance Center, and laboratories in 50 states, five cities, and Puerto Rico.

Public Health Surveillance

Public health surveillance—the collection, analysis, and use of data to target public health prevention and intervention activities—is the foundation of public health practice at CDC, and continues to represent CDC’s core work, whether as detective work in the field, or advanced analysis to understand disease transmission. CDC uses electronic data systems to monitor population health information around the clock to detect and track diseases. For example, following 9/11, CDC invested in using health-related data based on syndromic surveillance in Emergency Departments as an early warning system for a bioterrorist attack. Those investments are paying dividends, as this information technology system now allows officials to detect a wide range of health threats beyond biological attacks, from opioid overdoses to chemical exposures to disease outbreaks.

To ensure a nationwide surveillance capability, CDC supports surveillance infrastructure, including information technology systems, and practice at the state and local levels through the National Notifiable Disease Surveillance System, the National Syndromic Surveillance Program, the National Healthcare Safety Network, the Emerging Infections Program Active Bacterial Core Surveillance, and components of national influenza surveillance.

Beginning in fiscal year 2016, Congress recognized the large and growing threat of antibiotic resistance and appropriated funding for CDC to detect and respond to resistant pathogens, prevent the spread of resistant infections, and collaborate with partners to encourage innovation with respect to new prevention strategies.

CDC has multiple surveillance systems that can detect and track resistant threats across healthcare, food, and community settings.

CDC’s Global Disease Detection Operations Center monitors outbreaks 24/7, assesses their potential risk to the United States and communities around the world, and improves global public health surveillance. Since 2017, CDC has tracked more than 170 unique diseases globally and identified outbreaks in more than 190 countries. CDC works with the 17 Phase 1 and the 14 Phase 2 Global Health Security Agenda partner countries to help them build the core public health capacities necessary for identifying and containing outbreaks before they become epidemics that could affect us all. The 17 Phase 1 countries receive direct financial support and technical assistance from CDC; the 14 additional countries receive only technical assistance from CDC. Our work through the Global Health Security Agenda emphasizes four critical areas: surveillance, laboratory, workforce development, and rapid response capability. In addition, CDC medical and public health officers staff United States Quarantine Stations that are located at 20 United States ports of entry and land-border crossings where the majority of international travelers arrive. These health officers are an important defense to prevent the introduction into, and spread of infectious diseases in, the United States.

Respond

CDC’s number one priority during any public health emergency is to protect the health of the public. CDC subject matter experts respond regularly to events such as foodborne outbreaks, natural occurring anthrax and botulism cases, smallpox vaccine adverse event cases, and seasonal influenza. CDC’s readiness activities, expertise, and infrastructure

provides the foundation for all types of public health emergency responses and is scalable and can surge to respond to events such as the 2013 meningitis outbreaks. The expertise and systems used in such responses can be augmented further for larger public health emergency responses such as the 2009 H1N1 response, 2014 Ebola response, and the Zika response.

State and local public health agencies are the front lines of public health preparedness and response. CDC provides ongoing technical assistance and, where requested, on-the-ground personnel and materials to assist with response efforts. CDC's established relationships with state and local health departments ensure that day-to-day public health systems function effectively and efficiently, and that emergency response actions are appropriate to the threat. These continuous relationships, between and during emergency responses, ensure a level of trust and collaboration that cannot be overemphasized. During the stress of an emergency response, having a trusted partner you can turn to immediately can mean the difference between life and death for patients, and ensures the rapid delivery of public health services, such as vaccinations and clean water, for communities.

CDC experts lead and staff every activation of the agency's Emergency Operations Center (EOC), ensuring response activities are effective and efficient. CDC has activated its incident management system for 67 responses over the last 16 years. During a response, in coordination with and, sometimes at the direction/request of the Office of the HHS Assistant Secretary for Preparedness and Response, CDC's EOC rapidly deploys scientific experts, coordinates the delivery of supplies and equipment to the incident site, monitors response activities, provides resources to state and local public health departments, and disseminates timely and accurate information within government, to health care providers and to the public. During the agency's Ebola and Zika responses, 3,700 and 1,700 CDC staff participated in the response, respectively. During the Ebola response, CDC staff completed over 2,000 field deployments to West Africa. CDC also responds to public health events that do not require EOC support. In fiscal year 2017, CDC assisted state, local, and overseas public health authorities in 38 epidemiologic investigations of emerging infectious disease outbreaks. In addition, the Global Rapid Response Team, stood up following the 2014 Ebola outbreaks, has over 400 ready and rostered experts.

Since its inception, that team has provided nearly 9,000 person-days of support for response activities.

We are committed to continuously improving our response capability. After each activation, whether for a real event or exercise, we conduct a thorough after-action review to identify strengths to sustain and areas for improvement. Use of this information is key to improving performance for the next incident or event.

Conclusion

I want to leave the Committee with three primary points about CDC's role in biopreparedness.

- 1) Our responses are built on our longstanding partnerships with state, local, and international public health authorities;
- 2) Our detection capabilities and surveillance programs are based on our broad and deep scientific, medical, and programmatic expertise; and
- 3) Our response capacity ensures timely aid to state and local public health systems in times of crisis.

CDC has 72 years of experience in bringing top scientific expertise to health emergencies and remains a trusted partner in the United States and around the world. CDC stands ready to do its part to protect the health and well-being of the American public and save lives. We cannot necessarily predict the next disaster, but we know that being prepared protects health, saves lives, and prevents economic losses.

Thank you for the opportunity to testify.

* * *

Mr. HARPER. Thank you, Dr. Schuchat.

The chair will now recognize Dr. Fauci for 5 minutes for your opening statement.

TESTIMONY OF ANTHONY FAUCI, M.D.

Dr. FAUCI. Thank you very much, Mr. Chairman.

Chairman Harper, Ranking Minority DeGette, members of the committee, thank you very much for giving me the opportunity today to present to you the role of the National Institute of Allergy and Infectious Diseases in addressing biodefense and emerging infectious diseases.

Our role in this really dates back many years, but was really solidified following the attacks of 9/11 with the anthrax attacks, which prompted us, together with our colleagues at HHS, to develop a strategic plan and a research agenda. For our role in that, as you know, the NIH for years, with regard to any emerging infectious disease, is involved in having a number of approaches, stemming from basic and clinical research, research resources for both industry and academic communities, with the ultimate goal of developing vaccines, therapeutics, and diagnostics.

We have been in a very strong partnership with BARDA in developing the concepts for interventions, which were then handed over to them for advanced development.

This slide just shows a representative example of some key achievements directed specifically at the category A agents that were in our strategic plan. Very briefly, for example, a better smallpox vaccine, next-generation vaccines for anthrax, antitoxins for botulism, antibiotics for plague, and, interestingly, the development of an Ebola vaccine, which long antedated the outbreak that we experienced in West Africa in 2014.

Having said that, it is important to point out, as we have in the past and as shown in this interesting article from Newsday of 2001, the worst bioterrorist may actually be nature itself.

It is interesting to point out, Mr. Chairman, that I have been testifying before this committee for the last 33 years. The first time I did, I drew a map, and it's shown here. And the reason I drew the map is I wanted to point out that there would be emerging and reemerging infectious diseases. And the first time I testified before this committee, I put HIV on the map as shown there.

Today, the map is the same structurally, but this is what it looks like. And these are the emerging and reemerging infectious diseases. Many of them, many of them are curiosities and are not really of great public health impact, but others are really important and we've experienced them recently, such as Ebola, Zika, and the threat of a pandemic influenza.

Now, let's take one of these, Ebola. You mentioned in your opening statement, as others have, about the West Africa outbreak and the recent outbreak in the Democratic Republic of the Congo. It's important that the CDC, the NIH, and other agencies of the Public Health Service responded very rapidly there.

One thing that was proven that's important is that you can do good research in the context of an outbreak. And we developed, with others, a vaccine, which is called the VSV vaccine, which was first tried in a Phase I trial right in Bethesda at the NIH Clinical Center, and then went over to Africa in a Phase II trial. This is the vaccine that was used in the ring vaccination program that was actually involved in the West Africa outbreak.

If you then fast forward a couple of years to where we are today, with the outbreak in the Democratic Republic of the Congo, we have actually learned a lot and are applying what we learned to that. Let me give you an example. The experimental vaccine that was used in the ring vaccination program has now been deployed to the Democratic Republic of Congo, and even as we speak today, it is being used in a ring vaccination with 50 rings and 150 vaccinations per ring.

Interestingly, and as I mentioned before we came, that in 1995, there was an outbreak in Kikwit in the Democratic Republic of the Congo. To just show you the connection between clinical care and research, we brought one of the survivors of Kikwit to Bethesda, took their B cells, cloned it, made a monoclonal antibody. And now the Democratic Republic of the Congo has asked us to ship that to them for their discretion use as a countermeasure in the epidemic. So it came full circle that our collaboration with them came back with something that perhaps could help them.

I want to close in the last couple of seconds with influenza. I wrote this article just a few months ago, talking about the need for a universal flu vaccine. And, in fact, we have developed a strategic plan and a research agenda because of the threat, not only of getting a better seasonal flu vaccine, but also a threat of a pandemic. And we could only do that with a vaccine that essentially is able to protect us against all subtypes of influenza.

And I'll close on this last slide—this is not working very well, sorry—which is an article that I actually wrote 17 years ago, but it's very relevant today. And what it says is that emerging infections are a perpetual challenge. We've always had them, we have them now, and we always will have them. So if they are a perpetual challenge and a perpetual risk, we must meet them with perpetual readiness and, hopefully, we'll be able to do that.

Thank you.

[The prepared statement of Dr. Fauci follows:]

**DEPARTMENT OF HEALTH AND HUMAN SERVICES NATIONAL
INSTITUTES OF HEALTH, NATIONAL INSTITUTE OF ALLERGY AND
INFECTIOUS DISEASES RESEARCH ADDRESSING BIODEFENSE AND
EMERGING AND RE-EMERGING INFECTIOUS DISEASES, TESTIMONY
BEFORE THE HOUSE COMMITTEE ON ENERGY AND COMMERCE,
SUBCOMMITTEE ON OVERSIGHT AND INVESTIGATIONS**

Anthony S. Fauci, M.D.

Director of the National Institute of Allergy and Infectious Diseases

June 15, 2018

Mr. Chairman, Ranking Member DeGette, and members of the Subcommittee, thank you for the opportunity to discuss the research response of the National Institutes of Health (NIH) to potential attacks with chemical and radiological/nuclear agents as well as biological threats, including emerging and re-emerging infectious diseases. I direct the National Institute of Allergy and Infectious Diseases (NIAID), the lead NIH institute for biodefense research.

The NIH conducts and supports basic and clinical research to better understand the biological effects of, and to develop medical countermeasures (MCMs) for, chemical, biological, and radiological/nuclear threats. Most of this work is conducted by the NIAID at the NIH. NIAID supports basic research on microbiology and immunology as well as applied and clinical research to evaluate candidate MCMs including diagnostics, therapeutics, and vaccines. This strategic effort includes the pursuit of foundational platform approaches that could be used to develop MCMs against multiple threats or pathogens. These platforms include molecular biological technologies for vaccines, targeted antibody therapeutics, and broad-spectrum antibiotics and antivirals.

NIH coordinates its biodefense research with partners in industry, academia, and the Federal Public Health Emergency Medical Countermeasures Enterprise (PHEMCE) to ensure that promising countermeasures for biological, chemical, and radiological public health threats can proceed to advanced development. Since fiscal year 2012, NIH has supported the early development of more than 20 candidate MCMs for high-priority threats, and ultimately transitioned support for those candidate MCMs to the Biomedical Advanced Research and Development Authority (BARDA) for advanced development, with the goal of Food and Drug Administration (FDA) approval, licensure, clearance, or authorization, and for potential inclusion in the Strategic National Stockpile. NIH funding for emerging infectious disease, including biodefense, research was approximately \$2.6 billion in FY 2017.

NIH Medical Countermeasure Development

Innovative technologies and approaches supported by NIH are enabling the development of new medical countermeasures (MCMs) at an unprecedented pace. High-throughput sequencing and platform-based technologies are facilitating the development and manufacture of MCM candidates to expedite their clinical evaluation. For example, during the Zika virus

outbreak in the Americas, NIAID scientists used Zika virus genetic sequence information to develop a vaccine candidate that moved from concept to first-in-human trial in less than four months – likely the shortest development period ever for such a vaccine. The vaccine was developed with a readily deployable DNA vaccine platform that is a form of gene-based immunization previously employed by NIAID to develop a candidate vaccine for West Nile virus. These types of genetic platforms could be used to respond similarly to multiple emerging and re-emerging infectious disease threats.

Other broad-spectrum approaches are being used to advance the development of therapeutics that could be used against multiple pathogens. For example, NIAID has supported development of broad-spectrum antiviral agents such as BCX4430 (galidesivir), which has demonstrated activity against Ebola and other RNA viruses, and broad-spectrum antibacterial products, including a compound with activity against the two different bacteria that cause tularemia and plague.

NIAID continues to explore other inventive approaches to treat or prevent bioterrorism threats. Monoclonal antibodies, which precisely bind to a single target, have been used to treat certain cancers, infectious diseases, and autoimmune diseases. Monoclonal antibodies also have the potential to treat emerging and re-emerging infectious diseases, and as a first line intervention to prevent or slow the progress of infectious disease outbreaks as vaccines are being developed. A notable example is ZMapp™, a cocktail of three monoclonal antibodies targeting Ebola virus. ZMapp™ showed promise as a treatment for Ebola virus disease in an NIAID-supported clinical trial during the 2014-2016 outbreak in West Africa. Another innovative approach specific to vaccine development is the use of adjuvants. Adjuvants are valuable tools that can boost immune responses to otherwise modestly effective vaccines, and potentially can expedite development of vaccines for emerging pandemic threats. NIAID supports programs for discovery and development of adjuvants that have led to 50 novel adjuvants and 18 vaccine clinical trials.

NIAID also has invested in critical infrastructure and research resources to encourage the development and testing of biodefense MCMs. NIAID supports research capacity at high-containment laboratories where dangerous pathogens can be studied safely. In addition, NIAID provides qualified scientists with research resources, including microorganisms, research reagents, and preclinical development services that can fill knowledge gaps. These programs lower the financial risk for potential commercial partners and expedite the development of MCMs.

These NIH-supported activities are advancing a robust pipeline of candidate MCMs needed to ensure the development of safe and effective products to protect the public health. Notable successes are outlined below.

Ebola

NIAID partnered with the government of Liberia to establish the Partnership for Research on Ebola Virus in Liberia (PREVAIL). This clinical research partnership enabled a series of clinical trials, including studies testing several Ebola virus therapeutic and vaccine candidates, among them ZMapp™ and the cAd3-EBOZ vaccine developed by the NIAID Vaccine Research Center (VRC) in partnership with industry. Several Ebola countermeasure candidates developed by NIAID have transitioned to BARDA for advanced development, including a novel vaccine approach using two candidate vaccines in a prime-boost regimen.

NIAID currently is utilizing its expertise in Ebola research to respond to the ongoing Ebola outbreak in the Democratic Republic of the Congo (DRC). NIAID is providing technical assistance to the DRC-World Health Organization (WHO) effort to plan and implement a research response to the outbreak, including vaccine, therapeutics, and diagnostic research. NIAID also has developed as a therapeutic candidate mAb114, a monoclonal antibody active against Ebola. The antibody, which has shown promise in animal testing, was originally isolated from a survivor of the 1995 Ebola outbreak in Kikwit, DRC, through a research partnership between the NIAID VRC and the DRC's Institut National de Recherche Biomédicale. At the request of the Minister of Health of the DRC, NIAID is providing courses of mAb114 for treatment of Ebola Virus Disease, with specific research protocol design to be determined.

NIAID also has deployed a team to the National Public Health Laboratory in nearby Brazzaville, Republic of the Congo, to establish additional Ebola diagnostic and sequencing capacity in case the epidemic spreads to that country.

Nipah

NIAID conducts and supports research on countermeasures for Nipah, a deadly virus with case fatality rates of 40 to 75 percent. NIAID researchers have developed a candidate Nipah vaccine that was shown to protect against infection in a monkey model. NIAID-funded researchers, in collaboration with NIH scientists, discovered a potential monoclonal antibody treatment for Nipah virus. This treatment candidate, m102.4, effectively protected ferrets and non-human primates after exposure to Nipah virus. Based on this research, NIAID is assisting with the research response to the ongoing Nipah virus outbreak in India. At the request of the WHO, NIAID researchers have been working with scientists and clinicians from India to develop a clinical trial protocol to test the experimental monoclonal antibody m102.4 against Nipah virus. NIAID researchers also have evaluated an antiviral treatment for Nipah virus in collaboration with CDC and industry. This candidate, GS-5734, has been shown to protect against Nipah virus disease in monkeys.

Smallpox

NIAID supported the early-stage development of a novel smallpox vaccine, IMVAMUNE®, and a therapeutic, TPOXX® (tecovirimat), prior to their transition to BARDA for advanced development. IMVAMUNE® was shown to produce a superior immune response compared to the currently licensed smallpox vaccine. TPOXX® currently is under consideration for FDA approval pursuant to the Animal Rule, using pivotal animal model data supported by NIAID.

Anthrax

NIAID supported the preclinical and clinical development of the anthrax countermeasure ANTHIM® (oblitoxaximab), prior to its transition to BARDA for advanced development. ANTHIM® was approved by the FDA in 2016 for the treatment and prevention of inhalational anthrax, the deadliest form of the disease. NIAID also has supported the development of AV7909, a third-generation anthrax vaccine with a dry formulation that is easy to store and has increased shelf life. AV7909 has been transitioned to BARDA for further development.

Pneumonic Plague

NIAID supported critical animal model studies of ciprofloxacin and levofloxacin for FDA approval, pursuant to the Animal Rule, as treatments for pneumonic plague. In addition, NIAID scientists conduct foundational research on the bacteria that cause plague, and the fleas that transmit them, to understand plague biology and to aid in the design of new MCMs.

Pandemic Influenza

NIAID is partnering with BARDA to support the development of vaccine candidates for influenza strains with the potential to cause a pandemic, including H7N9 avian influenza. NIAID also is working to develop broadly protective, or “universal,” influenza vaccines that could protect against multiple strains of seasonal and pandemic influenza. NIAID recently developed a Strategic Plan to guide research efforts focused on the design and development of universal influenza vaccines.

Radiological/Nuclear Threats

NIH investment in radiation/nuclear research revitalized physician training and infrastructure for studying radiation injury and developing effective medical countermeasures. Since 2005, NIAID has transitioned 29 radiation/nuclear countermeasure candidates to BARDA for advanced development. Recent successes include FDA approval of NEUPOGEN® (filgrastim) and Neulasta® (pegfilgrastim) to treat radiological or nuclear injuries. In addition, NIAID is funding animal studies of Nplate® (romiplostim) for acute radiation syndrome for consideration for FDA approval under the Animal Rule.

Chemical Threats

NIAID administers a trans-NIH chemical countermeasures program that supports research and development of therapeutics for people exposed to dangerous chemicals, including nerve agents such as Sarin and VX; metabolic poisons such as cyanide; chemicals affecting the skin, eyes, and mucous membranes such as sulfur mustard; chemicals affecting the respiratory tract such as chlorine; and toxic industrial chemicals. NIH recently transitioned several candidate therapeutics to BARDA for advanced development, including those for nerve agent poisoning (midazolam and galantamine), sulfur mustard exposure (tissue plasminogen activator), and inhalation chlorine exposure (R-107 and GSK2798745).

Conclusion

NIAID has moved strategically toward a MCM research paradigm that features broader, more flexible platform technologies. This effort is yielding significant scientific advances that help protect against multiple emerging public health threats, whether man-made or naturally occurring. Together with academia, industry, and PHEMCE partners, NIAID remains committed to meeting public health emergency needs by advancing high-priority research toward development of MCMs for radiological/nuclear, chemical, and biological threats, including emerging and re-emerging infectious diseases.

Mr. HARPER. Thank you very much.

We now have the privilege of hearing from Rear Admiral Denise Hinton.

Admiral Hinton, you are recognized for 5 minutes.

TESTIMONY OF REAR ADMIRAL DENISE HINTON

Admiral HINTON. Thank you.

Chairman Harper, Ranking Member DeGette, and members of the committee, thank you for the opportunity to appear today to discuss the state of biopreparedness.

Medical and public health preparedness and response is critically important to the health and security of our nation. And I am pleased to be here today to discuss how FDA is working towards the shared goal of making sure that we have the medical products necessary to protect our nation from a range of public health threats, whether naturally occurring, accidental, or deliberate.

The outbreak of Ebola virus disease in the Democratic Republic of the Congo serves as a reminder that biological threats can and often do emerge with little to no warning and can rapidly become global challenges. I can assure you that FDA is dedicated to helping end this outbreak as quickly as possible, as we are actively engaged in supporting international response efforts.

FDA plays a critical role in facilitating preparedness for and response to biological threats. Our role focuses largely on facilitating the development and availability of medical countermeasures, or MCMs, such as vaccines, therapeutics, and diagnostic tests to protect against and respond to these threats.

Toward that end, we work closely with our HHS partners testifying here with me today as well as other U.S. Government partners, product developers, and nongovernmental organizations to facilitate the development and availability of MCMs. FDA also works closely with the Department of Defense to facilitate the development and availability of MCMs to support the needs of our nation's military personnel.

Prior to joining FDA and the U.S. Public Health Service Commissioned Corps, I proudly served as an officer in the United States Air Force. So these efforts are near and dear to me, and we are fully committed to closely working with our colleagues at the DOD to support the unique needs of the U.S. military personnel.

At FDA, we have made it a priority to utilize our authorities to proactively work with our private sector and government partners to help facilitate the translation of discoveries in science and technology into safe and effective MCMs as part of advancing public health and strengthening our national security.

We share Congress' goal of having safe and effective MCMs available in the event that they are needed, and we have made significant progress toward this important goal. For example, since 2012, FDA has approved, licensed, or cleared more than 120 MCMs, including supplemental changes to already approved products and modifications to diagnostic devices for a diverse array of threats, including anthrax, botulinum toxin, plague, smallpox, and pandemic influenza.

We have also issued more than 60 emergency use authorizations since 2005 to enable access to products to respond to threats, including for Zika virus, Ebola virus, H7N9 influenza virus, and the Middle East Respiratory Syndrome Coronavirus.

While the close collaboration and coordination among the agencies represented here today has achieved many successes in the development of MCMs, I would emphasize that developing MCMs is highly complex and there remain regulatory science gaps that can challenge development programs, such as a lack of models and biomarkers to enable the extrapolation of data generated in animal models to humans. Without such tools, it is difficult to generate the data necessary to support regulatory decisionmaking.

Addressing these regulatory science gaps remains a high priority for the FDA, and we have established a broad and robust portfolio of cutting-edge research under our MCMs Initiative regulatory science program to develop these tools and to promote innovation in the development of MCMs.

FDA is acutely aware that biothreats can emerge from an accidental release or exposure to threat agents during the course of conducting research. As such, we are working to ensure that our laboratories and workplaces are operated in a safe and secure manner to protect employees, the surrounding communities, and the environment. As the FDA's chief scientist, I can assure you that the laboratory safety is a high priority for me and the agency.

FDA remains deeply committed to working closely with its partners and fully using the authorities Congress provides to help facilitate and accelerate the development and availability of safe and effective medical countermeasures. While we have made significant progress, we know that more work remains to be done. We look forward to partnering with Congress and stakeholders as we work together to further enhance biopreparedness.

Thank you for inviting me to testify today. I look forward to answering any questions you may have.

[The prepared statement of Admiral Hinton follows:]

**TESTIMONY OF REAR ADMIRAL DENISE HINTON CHIEF SCIENTIST,
FOOD AND DRUG ADMINISTRATION, DEPARTMENT OF HEALTH AND
HUMAN SERVICES, BEFORE THE COMMITTEE ON ENERGY AND
COMMERCE, SUBCOMMITTEE ON OVERSIGHT AND INVESTIGATIONS,
UNITED STATES HOUSE OF REPRESENTATIVES, "THE STATE OF U.S.
PUBLIC HEALTH, BIOPREPAREDNESS: RESPONDING TO BIOLOGICAL
ATTACKS, PANDEMICS, AND EMERGING INFECTIOUS
DISEASE OUTBREAKS," JUNE 15, 2018**

Introduction

Chairman Harper, Ranking Member DeGette, and members of the committee, thank you for the opportunity to appear today to discuss the Food and Drug Administration's (FDA or the Agency) efforts to prepare our Nation to respond to biological threats, such as biological

weapons and naturally-emerging infectious diseases, like pandemic influenza, Zika virus, and Ebola virus.

Biological threats—whether deliberate, naturally occurring, or accidental—can and often do emerge with little to no warning. This was the case with the anthrax attacks of 2001, the 2009 H1N1 influenza pandemic, the 2014 Ebola outbreak in West Africa, the emergence of Zika virus in 2016, and the recent Ebola outbreak in the Democratic Republic of Congo (DRC), to name just a few.

We are continually reminded that biological threats know no borders, and that biological threats can rapidly become global challenges. As such, we must remain vigilant and continue to work to optimize our preparedness and response capabilities.

FDA's Public Health Preparedness and Response Mission

FDA plays a critical role in facilitating preparedness for, and response to, biological threats (as well as chemical, radiological, and nuclear (CBRN) threats). FDA's role focuses largely on facilitating the development and availability of medical countermeasures—such as vaccines, therapeutics, and diagnostic tests—to protect against, and respond to, these threats.

FDA works closely with its HHS and other U.S. government partners through the Public Health Emergency Medical Countermeasures Enterprise (PHEMCE), as well as with regulated industry and non-governmental organizations (NGOs), to sustain and optimize the medical countermeasure framework necessary to effectively respond to public health emergencies. FDA also works closely with the Department of Defense (DoD) to facilitate the development and availability of medical countermeasures to support the unique needs of our nation's military personnel.

FDA's operations within its medical countermeasures mission cover a broad range of activities vital to facilitating the development of, and access to, safe and effective medical countermeasures, including:

- Reviewing marketing applications for medical countermeasures and approving those that meet standards for safety and efficacy;
- Providing regulatory advice, guidance and technical assistance to sponsors developing medical countermeasures, as well as to U.S. government partners, international regulators, and international organizations such as the World Health Organization;
- Supporting efforts to establish and sustain an adequate supply of medical countermeasures, including averting supply disruptions when feasible and, in certain situations, allowing products to be used beyond their labeled expiration dates when supported by appropriate scientific evaluation;
- Enabling access to medical countermeasures that are not yet approved—when necessary— through an appropriate mechanism, including through FDA's Emergency Use Authorization (EUA) authority;
- Proactively identifying and resolving regulatory challenges associated with medical countermeasure development and ensuring that FDA regulations and policies

adequately support timely medical countermeasure development and enable preparedness and response activities and capabilities;

- Fostering the professional development of FDA scientists to ensure that FDA personnel maintain the skills and abilities to support the medical countermeasure mission; and
- Supporting regulatory science to create the tools, standards, and approaches necessary to develop and assess the safety, efficacy, quality, and performance of medical countermeasures.

Fostering Medical Countermeasure Development and Availability

FDA's Medical Countermeasures Initiative (MCMi)—established in 2010—brought enhanced resources to FDA that enabled FDA to hire additional expert staff, and to become more deeply and thoroughly engaged in medical countermeasure activities. This program continues to be key to providing certainty regarding regulatory pathways for medical countermeasures, advancing medical countermeasure regulatory science to support regulatory decision-making, and advancing important policies and mechanisms to facilitate the timely development and availability of medical countermeasures.

At FDA, we fully appreciate that the development of medical countermeasures can present complex and unique challenges. FDA's increased engagement in medical countermeasure activities has helped to resolve many challenges associated with medical countermeasures development so that programs continue to move forward. For example, since 2012, FDA has approved, licensed, or cleared more than 120 medical countermeasures (including supplemental changes to already approved applications and modifications to diagnostic devices) for a diverse array of threats including anthrax, botulinum toxin, plague, smallpox and pandemic influenza. Thirteen of these medical countermeasures have been approved under the Animal Rule, which enables animal efficacy studies to substitute for efficacy trials in humans if the results can reasonably be extrapolated to the expected human use.¹ These approvals underscore the critical role the Animal Rule and animal studies can play in advancing medical countermeasures for some of the most challenging threats. And of note, through the use of regulatory science, FDA was able to approve inhalational anthrax therapeutics and a botulism antitoxin for use in children as well as adults, despite the fact that ethical concerns precluded studying pediatric patients in clinical trials.

In the area of pandemic influenza preparedness, FDA has approved several influenza diagnostic tests, which can help facilitate an effective response to an influenza pandemic by rapidly identifying infected persons and facilitating appropriate care. In addition, FDA has approved several seasonal influenza vaccines, helping increase and sustain pandemic influenza vaccine production capacity. These approvals include the first seasonal influenza vaccine produced using modern cell culture techniques licensed in the United States, and the first seasonal influenza vaccine made through recombinant deoxyribonucleic acid (DNA)

¹ To date, a total of 13 medical countermeasures have been approved under the Animal Rule, including inhalational anthrax therapeutics, a botulism antitoxin, antibiotics for the treatment and prophylaxis of plague, and treatments for acute radiation syndrome, prophylaxis against the lethal effects of soman nerve agent poisoning, and treatment of known or suspected cyanide poisoning.

technology. Both of these vaccines offer an alternative to the egg-based process and a potential for a faster manufacturing startup in the event of a pandemic. FDA also approved the first adjuvanted influenza vaccine for use in people 18 years of age and older who are at increased risk of exposure to the avian influenza H5N1 virus subtype contained in the vaccine. This vaccine is not for commercial distribution but will be part of the national stockpile in the event it is needed. Furthermore, FDA has continued to collaborate closely with the Biomedical Advanced Research and Development Authority (BARDA), the National Institute of Allergy and Infectious Diseases (NIAID), and the Centers for Disease Control and Prevention (CDC) on developing avian influenza H7N9 virus vaccine candidates.

Additionally, FDA approved the first intravenous antiviral drug to treat acute, uncomplicated influenza infection in adults and expanded its indication to include treatment of children ages two years and older. FDA also expanded the indications for use of the influenza antiviral, oseltamivir, to treat children as young as two weeks of age.

FDA also continues to facilitate the development of products to address antimicrobial resistance, including antibacterial drugs to treat patients with antimicrobial resistant infections, vaccines that can help prevent the emergence and spread of antimicrobial resistance, and diagnostic tests that can help rapidly identify the appropriate treatment for infected individuals. For example, FDA has been implementing Title VIII (Generating Antibiotic Incentives Now (GAIN)) of the Food and Drug Administration Safety and Innovation Act (FDASIA) since it became law in July 2012. GAIN created incentives to help develop new antibacterial and antifungal drugs intended to treat serious or life-threatening infections. Those meeting requisite criteria are determined to be qualified infectious disease products (QIDPs).² FDA has granted 147 QIDP designations through the end of FY 2017—approximately 74 of which were for novel drugs. Since the enactment of GAIN, 12 QIDPs have been approved.

With respect to supporting the development of diagnostic tests for antimicrobial resistant threats, FDA and CDC have collaborated to develop the AR Isolate Bank, a centralized repository of microbial pathogens with well-characterized resistance profiles. The AR Isolate Bank, which currently contains three bacterial isolate panels of pathogens of national medical concern (representing more than 160 total pathogens), provides a valuable resource to biotech and diagnostic groups in researching, designing, validating and evaluating next generation clinical tests. These tests in turn may support earlier diagnosis and development of more effective treatment options that can slow antibiotic resistance. As of January 2018, the AR Isolate Bank shipped more than 2,000 isolate panels.

There are still regulatory science gaps that can challenge development programs, however, such as a lack of animal models to support medical countermeasure development or insufficient biomarkers to enable the extrapolation of data generated in animal models to humans. Without such tools, it is difficult to generate the data necessary to support regulatory decision making. Given the urgency inherent in our medical countermeasure work, addressing these regulatory science gaps remains a high priority for the Agency.

To that end, FDA has established a broad and robust portfolio of cutting-edge research under the MCMi Regulatory Science Program to help develop these tools and promote

² A QIDP is defined as an antibacterial or antifungal drug for human use intended to treat serious or life-threatening infections, including those caused by an antibacterial or antifungal resistant pathogen, including novel or emerging infectious pathogens.

innovation in the development of medical countermeasures. A few examples of projects include: supporting the development of “organ-on-a chip” models to assess radiation damage in lung, gut, and bone marrow, and then using these models to test candidate medical countermeasures; collaborating to establish a publicly-available genomic sequence reference database for use by developers seeking to validate candidate multiplex *in vitro* diagnostic tests that could be used to diagnose multiple pathogens simultaneously (FDA-ARGOS); developing reference materials for developers to use to validate nucleic acid-based and serological diagnostic tests for Zika virus; supporting a project to identify and correlate biomarkers of host response to Ebola virus infection in animal models and humans to support medical countermeasure development; developing methods for obtaining safety and limited efficacy data from patients who receive medical countermeasures during public health emergencies; and establishing the Animal Model Qualification Program designed to support medical countermeasure development by promoting the development of animal models for use across multiple product applications, thereby minimizing duplication of effort and resources.

FDA is acutely aware that biothreats can also emerge from accidental release or exposure to threat agents during the course of conducting research. As such, the Agency works to ensure that its laboratories and workplaces are operated in a safe and secure manner to protect employees, the surrounding communities, and the environment. This includes ensuring that FDA is in compliance with the Select Agent Regulations as well as with Federal, state, and local occupational safety and health requirements (as appropriate), and environmental regulations.

FDA also works to establish and sustain an adequate supply of medical countermeasures. For example, FDA supports the Shelf Life Extension Program (SLEP), a Federal fee-for-service program, for extending the useful shelf life of military-significant and contingency-use medical products, including medical countermeasures that are owned by components of DoD or other Federal program participants, such as the Strategic National Stockpile (SNS).³ FDA laboratory personnel test and evaluate drugs submitted for shelf-life extension to ensure stability and quality before a shelf-life extension is approved.

In addition, FDA works to ensure that the U.S. Government is as prepared as possible to rapidly deploy medical countermeasures when necessary. For example, FDA has worked with government partners to prepare for potential EUA authorization of stockpiled medical countermeasures against a diverse array of threats including smallpox, anthrax, and pandemic influenza.⁴

There are tremendous opportunities to continue to further the development of groundbreaking, innovative medical countermeasures, and the Agency intends to fully seize, and build upon, these opportunities.

³ SLEP is designed to defer drug replacement costs for date-sensitive stockpiles of drugs by extending their useful shelf life beyond the manufacturer’s original expiration date.

⁴ To facilitate the issuance of EUAs, FDA has developed a pre-EUA submission process. FDA works with product sponsors or government agencies, such as CDC and DoD, to develop pre-EUA packages that will form the basis of an EUA request and decision, when circumstances justify. Pre-EUA packages contain data and information about the safety and efficacy of the product, its intended use under an EUA, and information about the potential emergency situation that might unfold.

Responding to Threats

When threats emerge, FDA works proactively with U.S. government partners, medical product developers, and, as necessary, international partners (including the World Health Organization (WHO) and international regulatory counterparts) to respond. Key FDA response activities include accelerating the development of investigational medical countermeasures, when needed, by working with U.S. government agencies that support medical countermeasure development and medical product sponsors to clarify regulatory and data requirements. For example, FDA continues to work closely with U.S. government agencies, the international community, and product developers—providing regulatory advice, guidance, and technical assistance—to advance the development and availability of medical products, including vaccines and therapies, to address Ebola virus and Zika virus. These activities are essential not only for advancing the development of investigational medical countermeasures to respond to ongoing outbreak and epidemics, but also to improve response to future outbreaks and epidemics. For example, FDA worked closely with NIH in response to the 2014 Ebola epidemic in West Africa to design an innovative and robust common clinical trial protocol to evaluate the most promising investigational products for Ebola. The experience and information gained from those efforts have been instrumental in supporting a rapid response to the recent Ebola outbreak in the DRC.

FDA also works to protect the safety of the nation's blood supply and human cells, tissues, and cellular/tissue-based products for transplantation when threats emerge. For example, FDA worked closely with developers to make rapidly available two investigational tests for blood screening for Zika virus. One of those tests has since been approved.

Another key FDA response activity to emerging threats is to enable access to investigational medical countermeasures, when necessary, through an appropriate mechanism such as under an investigational new drug (IND) application, an Emergency Use Authorization (EUA), or under expanded access mechanisms when the clinical circumstances warrant. Enabling access to available medical countermeasures in response to emerging threats is a high priority for FDA and FDA uses its authorities to the fullest to help protect public health. For example, since 2013, FDA has issued nearly 40 EUAs to enable the emergency use of in-vitro diagnostic devices for H7N9 Influenza virus, Enterovirus D68 (EV-D68), Middle East Respiratory Syndrome Coronavirus (MERS-CoV), Ebola virus, and Zika virus.

FDA also works to protect consumers against fraudulent products claiming to prevent, treat or cure conditions associated with emerging threats.

Throughout these response activities, FDA works to establish and maintain good lines of communication with WHO and regulatory authorities in affected countries, as necessary, to enable technical and information exchange, and to make sure that the needs of the affected countries are understood and addressed.

Conclusion

At FDA, we have made it a priority to proactively work with our private sector and government partners to help facilitate the translation of discoveries in science and technology

into safe and effective medical countermeasures. FDA takes seriously its responsibility to help drive and foster innovation as part of advancing public health and strengthening our national security.

Active FDA involvement is essential to encouraging industry engagement in medical countermeasure development. Working closely with its partners and exercising the authorities Congress provides to the fullest extent, FDA remains deeply committed to protecting and promoting public health, both domestically and abroad, in response to public health threats.

FDA appreciates Congress's support in continually optimizing its authorities, and providing resources, to enable FDA to achieve its public health emergency preparedness and response mission. FDA stands ready to work with Congress and stakeholders to enable us to better achieve this critical work in our mission to protect the American people.

Thank you for inviting me to testify today. I look forward to answering any questions you may have.

* * *

Mr. HARPER. Thank you very much.

I ask unanimous consent that the contents of the document binder be introduced into the record and to authorize staff to make any appropriate redactions. Without objection, the documents will be entered into the record with any redactions that staff determines are appropriate.

It is now time for members to have the opportunity to ask you questions, and I will recognize myself for 5 minutes.

Let me begin by saying that in my 10 years of service in Congress, I don't know if I've ever been at a committee hearing with a better lineup of witnesses. And so thank you all for being here. We look forward to your responses today.

And this is a question that will go rather quickly for all of you. And for each witness, which biological threat is of greatest concern to you and why? Let's start with Dr. Bright and then go down.

Mr. BRIGHT. That's a difficult question. As Dr. Fauci has laid out, there are so many threats. They're constantly emerging. And I wish I could take some of them off the table, but they keep coming at us. And even more concerning is technology advancing so much that they can change the biological threats that we know today into something different that we may not be prepared for.

I think our greatest threat for any of those is our response capabilities and being able to respond to anything that comes our way.

Mr. HARPER. Dr. Schuchat, is there one biological threat that is at the top of your list? I know they're all important, but is there one that gives you the greatest concern?

Dr. SCHUCHAT. I think influenza needs to be at the top of my list. It can affect everyone rapidly and is constantly changing. And with pandemics, all of the population of the world can be susceptible. So the threat of a pandemic has to be at the top of the list, because it can all happen fast.

Mr. HARPER. Dr. Fauci.

Dr. FAUCI. My number one and maybe number two and number three is influenza also. I agree, for the reasons that Dr. Schuchat has mentioned.

When you have a respiratory virus that can be spread by droplets and aerosol, and then you have the situation if there's a degree of morbidity associated with that, you can have a catastrophe. We've experienced in real world those types of things. The one that we always talk about is the 1918 pandemic which killed between 50 and 100 million people.

It is likely that it would be an influenza, but if not influenza, an influenza-like respiratory virus. We had a scare with SARS. Fortunately, public health measures were able to contain it, but influenza first or something like influenza is the one that keeps me up at night.

Mr. HARPER. Admiral Hinton.

Admiral HINTON. Thank you for the question. I would say the threat that would keep me up at night would be the unknown. If we don't know what that threat may be, we have to be able to anticipate. So with the emerging spectrum of diseases, it would be the unknown that would keep me up at night.

Mr. HARPER. Thank you.

For each witness, what area of biopreparedness is of the highest priority and why? Dr. Bright.

Mr. BRIGHT. The area of biopreparedness of the highest priority would be the ability to rapidly detect something that has entered our community or has been used as a weapon. The sooner we detect something, the sooner we can turn on the machinery and call in the capabilities to begin making vaccines and drugs.

Mr. HARPER. Dr. Schuchat.

Dr. SCHUCHAT. I would say our global health security would be at the top of my list, because, as you know, a threat anywhere is a threat everywhere. And I think our greatest vulnerabilities are in the weakest countries of the world.

We saw in Ebola how rapidly West African countries were overwhelmed, and that was an issue for us as well. So I think being able to strengthen the ability of every country to be able to prevent, detect, and respond to threats is where I'd place my focus.

Mr. HARPER. Dr. Fauci.

Dr. FAUCI. I would agree with those two. But let me add an additional one that may not necessarily be my first, is in our ability to respond, for example, with a vaccine, the modern day 21st century technologies of platform technology, where you don't have to wait 6 to 7 months to get a vaccine, where you can really get it out there within a period of a couple of months, which is doable if we put our mind and our resources to it.

Mr. HARPER. Thank you.

Admiral Hinton.

Admiral HINTON. Our continued efforts in the Ebola, and then making sure that we contain it within the specific regions and not letting it cross the borders.

Mr. HARPER. Thank you.

Dr. Bright, if I could ask you, obviously, the need to rapidly respond to a biological threat is essential. Does the public health system have the capability to deliver and administer medical countermeasures rapidly and effectively in a timely manner as you sit there today?

Mr. BRIGHT. As we sit here today, we are much better and can respond much more quickly than we were in the past 10 years. We've built a national response capability and an international capability incorporating new sciences and technologies. There is a lot of room for improvement. It still takes too long to respond to respond adequately to protect everyone in our nation.

Mr. HARPER. Thank you very much.

I will now recognize the ranking member, Ms. DeGette, for 5 minutes for her questions.

Ms. DEGETTE. Thank you very much.

Well, building on the question by the chairman just now, Dr. Bright, what changes do we need to make to make the system for developing countermeasures work more effectively and efficiently? ASPR has been a good start, but, you know, where do we need to go?

Mr. BRIGHT. Well, given the 12 years' experience with ASPR and the enterprise, working across government and working with our public-private partnerships, we've learned a lot in the past 12 years. Not everything is working as effectively or efficiently——

Ms. DEGETTE. So what do we need to do?

Mr. BRIGHT. We need to improve our communications and our transparency and how we bridge our different agencies and bridge government with industry. We need to ensure there's consistency in funding and availability so the partners that we work with can better align their business models with our government models as well. And we need to improve the efficiency at which we communicate and respond to proposals and other contractual mechanisms that we use to work with our industry partners.

Ms. DEGETTE. Are efforts underway being made to do all of those things?

Mr. BRIGHT. Yes, efforts are underway.

Ms. DEGETTE. And is there something Congress can do to help you?

Mr. BRIGHT. Congress has been very generous with the authorities to date. There are things that we can do to improve our language in our other transactional authorities to be able to work more fluidly and flexibly with our industry partners, and we would be happy to submit language to assist in that.

Ms. DEGETTE. We would be delighted to have that language. That would really help.

Dr. Fauci, none of these hearings can go without me asking you about what's going on with pandemic flu. And you had said that we are getting closer to being able to develop a universal vaccine. And you've said that before, because you've been trying to do it for a long time.

What does your timeframe look like now and what are the barriers?

Dr. FAUCI. Congresswoman DeGette, the timeframe really varies about the level that you're talking about. There's not going to be one home run universal flu vaccine. There will be various iterations.

So I would say the timeframe. And I know every time when asked about a timeframe, people back off, and I don't want to get in court to be able to say something that's not going to be able to deliver. But since we spoke last, we have put into a Phase 2 trial a universal flu vaccine with a company called BiondVax, which is a multiple peptide prime followed by a killed vaccine boost.

Being in a Phase 2 trial means that you're another step closer to getting a product that you'll be able to use.

Ms. DEGETTE. Right.

Dr. FAUCI. So I would think that if you——

Ms. DEGETTE. How long is this trial going on for?

Dr. FAUCI. The trial will probably take—it's a Phase 2 trial, so that probably is going to take at least a year to determine if this induces the kind of response that you would predict would have some broad protection.

The first iteration of a universal flu vaccine is not going to be against all flu, absolutely. What we're hoping for is that the first iteration will cover, for example, all of a particular type, like all of the H3N2s. If we get that successful, then maybe all of the H1N1s.

There are two major groups of influenzas. The ultimate perfect one would be one that covers all of them. I think that's years and years and years away, but the first iteration may be 5 or so years away.

Ms. DEGETTE. And I'll ask you the same question I asked Dr. Bright. What can Congress do to help you?

Dr. FAUCI. I think Congress has been extraordinary in their positive effect on us in helping us. For example, in the 2018 omnibus, we were given an additional \$40 million to develop a universal flu vaccine, and we're getting additional money in the proposal of the House for our 2019 budget. So you've been very supportive and we really appreciate it.

Ms. DEGETTE. We think it's a high priority. I think I can speak for everybody in this room.

One more question. You're developing lots of different vaccines: smallpox, flu, anthrax, Ebola. How do you prioritize your efforts to target the pathogens and toxins that provide the greatest risk?

Dr. FAUCI. That's a very good question. We do two things, Congressman. We target specific pathogens based on the threat. If you're talking about a bioterror threat, it's the intelligence that we get. And if you're talking about the possibility of an emerging infection, it's very difficult to guess what's going to come out.

Ms. DEGETTE. Right.

Dr. FAUCI. So we know, and it was mentioned in one of the opening statements, that H7N9, for example, if you look at the CDC chart, it's way up there as a threat. So we clearly made an investment of a considerable amount of money to develop a vaccine for that.

But as I mentioned in answer to one of the other questions, it's to develop platform technologies that's applicable to any disease, as opposed to picking out all the diseases and preemptively making a vaccine. In other words, making a kind of a vaccine that you could easily apply to whatever is the outbreak.

Ms. DEGETTE. Thank you. Thank you, Mr. Chairman.

Mr. HARPER. The gentlewoman yields back.

The chair will now recognize Dr. Burgess for 5 minutes.

Mr. BURGESS. Thank you, Mr. Chairman, and thanks to our panel for being here today.

Dr. Fauci, I wasn't going to do it, but you brought it up. And you said sometimes you'll give a timeframe, and then if it doesn't work out, then people will point that out to you. A couple of years ago, I think you gave us an 18-month figure on a Zika virus vaccine. How close are we today?

Dr. FAUCI. Thank you for that question. So when you're proving that a vaccine works or not, in the classical way, you have to get what's called an efficacy signal. There has to be infections in the community to get an efficacy signal.

Right now, thankfully for the countries involved, the Zika infections have plummeted almost to very, very few. However, the Phase IIb trial that I spoke to you about some months ago is still ongoing, and it's accruing volunteers in the study. So there's an interesting possibility here.

Let's say there are not enough Zika cases to be able to get an efficacy signal. We have been in discussions, with a lot of help from the FDA, about the possibility that if we get a

considerable amount, and I say thousands of volunteers with safety data, immunogenicity data, namely inducing the kind of response that you would predict would be protective, and you bridge it to the animal studies, there's a possibility that they would at least consider that there would be an accelerated approval. You never can guarantee anything, but that's at least on the table.

So my short answer to your question, Congressman Burgess, is that we are on the road to getting a Zika vaccine, and I feel pretty confident about that.

Mr. BURGESS. And from the FDA's perspective, that expedited approval that was talked about, is that something we can look for?

Dr. FAUCI. Well, I'll let the FDA speak for themselves, but you never want to anticipate what they're going to do. You can just give them the data and the information that they ask for, but—

Mr. BURGESS. I may submit that in writing, because I do want to ask you about another—on the golly gee whiz slide that you put up with all of the things that can happen to us, enterovirus D68 was included on that list.

Dr. FAUCI. Yes.

Mr. BURGESS. And CDC has put out a paper on acute flaccid myelitis and the incidence of that. And I recognize that it's low, but it does seem to peak every other August. So as we are coming up on one of those every other Augusts, do we know any more about this illness and why it has had the effect that it has?

Dr. SCHUCHAT. Yes. The outbreak of severe respiratory disease in children from the enterovirus D68 a few years ago was of concern. It was contemporary with the outbreak of acute flaccid myelitis. Very difficult to confirm that one caused the other, but there's a good probability that they did.

The family of enteroviruses are known to be able to cause neuropathic problems. And when you have a very common set of infections, it could be that that was a real rare end of the spectrum among the common ones.

So I think we do need to be ready for that. Unfortunately, there are so many different enteroviruses that it's very difficult to pick one that you would necessarily focus on for countermeasure development. There's some work on antivirals that might be promising as having a broader protection, but that's the state of it right now.

Mr. BURGESS. As you'll recall, fairly frightening when that did occur, the concern we heard from parents.

Dr. SCHUCHAT. Exactly. It was happening the same time as Ebola in Africa. When the President visited CDC, he was briefed on Ebola and on enterovirus D68.

Mr. BURGESS. Admiral Hinton, let me ask you. When Ebola was really a much more significant problem, September of 2014, the monoclonal antibody ZMapp was in trials, and then FDA put a clinical hold on it. My understanding at the time, there was a Herxheimer-type reaction that was fairly severe and so we stopped looking at it.

Is there a way—when we've got a problem of that order of magnitude going on, I guess I want some reassurance that the regulatory side is not going to interfere with the delivery of what may be a very potent tool, because several people have mentioned ZMapp. I mean, it's now a recognized tool in the toolbox. Is that correct?

Admiral HINTON. That's correct. And Dr. Fauci can please feel free to add in, but that is correct. And the FDA is not there to be a roadblock; it's to ensure that the drugs are safe and efficacious. So the reasons behind that may not be privy to us, but we do make sure that we

have safe and effective available drugs on the market to treat these and in emergency situations as well.

Dr. Fauci.

Dr. FAUCI. So ZMapp was part of a randomized controlled trial that was run by the NIH. It was published in *The New England Journal of Medicine*. The results, because of the diminution of cases at the time, were very strongly suggestive of efficacy, but not enough to be statistically significant. So the trial is technically still on. And right now, in DRC, they could use ZMapp either on a trial or, if they want, as compassionate use. But it is available.

Mr. BURGESS. It is available. Thank you all very much. Thanks for your testimony this morning.

Mr. HARPER. The gentleman yields back, who also serves as the chair of our Health Subcommittee.

Mr. BURGESS. Mr. Chairman, I'm also going to ask unanimous consent to place into the record the report of the Independent Panel of the United States Department of Health and Human Services to the Ebola response from 2015.

Mr. HARPER. Without objection, so entered.

[The information has been retained in committee files and can be found at <https://docs.house.gov/meetings/IF/IF02/20180615/108422/HHRG-115-IF02-20180615-SD003.pdf>.]

Mr. HARPER. The chair now recognizes the gentlewoman from Illinois, Ms. Schakowsky, for 5 minutes.

Ms. SCHAKOWSKY. Thank you, Mr. Chairman. I want to agree with you, Mr. Chairman, that this is an extraordinary panel.

Dr. Fauci, 33 years before this committee, that's a long time, and we appreciate you every time we see you.

I also want Dr.—I looked this up. Dr. Schuchat, it looks like you're about 28 years. Is it more than that? How many?

Dr. SCHUCHAT. It's 30 in July.

Ms. SCHAKOWSKY. OK, 30 in July. And such experience in all of you. It's just really remarkable. I thank all of you for being here today.

I'm particularly concerned about the improper and overuse of antibiotics that's driving the growth of antibiotic resistance around the world. I noticed, Dr. Fauci, in your new map with all the lines, right at the top was antibiotic resistance on the left there.

I feel an obligation to raise this issue too for my sister and colleague, the late Louise Slaughter, who was always raising this issue. In the United States, somewhere between 20 and 50 percent of all antibiotic prescriptions in hospitals are either unnecessary or inappropriate. Evidence suggests that antibiotic stewardship programs in hospitals can improve prescribing practices and help reduce the occurrence of antibiotic resistance.

So I'm interested in hearing more from our witnesses on this program. Whoever wants to go first. Dr. Schuchat.

Dr. SCHUCHAT. Yes. The problem with antimicrobial resistance is a transformational challenge for us because it obviously threatens modern medicine. CDC has been investing in efforts to improve stewardship of antibiotics, and at this point, by our latest data, two out of three hospitals had an antibiotic stewardship program, which is a big increase from before. But we think that there's much more to be done.

In addition, we have 850 hospitals around the country are reporting on their antibiotic use data to the National Healthcare Safety Network. So we're tracking data.

What we find in the healthcare system is when you track antibiotic use and feed back to clinicians how they're doing, they can improve. A lot of clinicians are test takers, and we like to do really well on those tests. And so learning that we're not doing as well as our peers in terms of the appropriateness of our prescribing can help improve that.

We're also tracking resistance. And we've really invested, thanks to the congressional support, we've been able to invest in much better timely, accurate, quality antimicrobial resistance detection around the Nation. It's where we got those nightmare bacteria reports that we came out with recently.

So I would say that behavior change in clinicians is difficult, but we're making progress. And a stewardship program in every hospital is a good start, but it takes more than the hospital to make that happen. We need the whole plans, the outpatient prescribers as well, to be part of the system.

Ms. SCHAKOWSKY. But you're saying that we do have a tracking system now for clinicians, for hospitals?

Dr. SCHUCHAT. Right. In our National Healthcare Safety Network, I'm told that 850 hospitals are already reporting to us on their antibiotic use. It includes 80 VA hospitals and 30 military hospitals. And they're having that be part of their—it's voluntary, but it's part of their ability to monitor what's going on in their own institution and then look across institutions.

Ms. SCHAKOWSKY. What percentage of hospitals does that represent, do you know?

Dr. SCHUCHAT. I don't actually have that information, but we could get that for you.

Ms. SCHAKOWSKY. OK. Has the CDC identified any obstacles to successfully implementing stewardship programs? If so, how are you addressing those?

Dr. SCHUCHAT. I would say that incorporating the outpatient facilities in the stewardship is important. We also found that rural areas, critical areas, we're challenged in being able to do all the things that we recommend in terms of antibiotic stewardship.

Our program convened a batch of the rural or critical area hospital stewardship leads, who had figured out ways to make a difference, and we're working with them to share their best practices more broadly. So I would say that large hospitals are really on the case now, and helping the smaller facilities get up to speed is important.

Ms. SCHAKOWSKY. Thank you. In the remaining seconds, does anybody else——

Dr. FAUCI. Yes. How we address antibiotic resistance is really governmentwide, and it's a program called CARB, Combating Antibiotic-Resistant Bacteria, that was established years ago, a few years ago, that involves what Dr. Schuchat had mentioned regarding the CDC. It involves the FDA research component from the NIH to develop new drugs to understand the mechanisms of resistance to harness the immune system, but also an organization called CARB-X, which BARDA has a major role in.

So maybe, Rick, you want to just mention that briefly.

Mr. BRIGHT. Very briefly. So since 2010, BARDA has invested over a billion dollars in addressing the development of new antibiotics to address antimicrobial resistance. We have, just in the last year, had the first antibiotic drug licensed in our program. We have several more in Phase 2 and Phase 3.

We also realized that the early stage pipeline was not sufficient to have a stream of new candidates going into advanced stage development. So we did launch a public-private

partnership called CARB-X, in collaboration with NIAID, also sponsored by Wellcome Trust, now Bill and Melinda Gates Foundation in the U.K. Government. So we have now funded 34 different novel technologies to address new mechanisms of action for new antibiotics and vaccines.

Ms. SCHAKOWSKY. Thank you. My time is up, but I hope that in addition to development, that we're looking at prevention here as well.

Thank you for your courtesy, Mr. Chairman. Thank you.

Mr. HARPER. Thank you. The gentlewoman yields back.

The chair will now recognize the chair of the House Ethics Committee and a valuable member of this subcommittee, the gentlewoman from Indiana, Mrs. Brooks, for 5 minutes.

Mrs. BROOKS. Thank you, Mr. Chairman.

Dr. Schuchat, and if, Rear Admiral Hinton, if you could pass that binder, please, over to Dr. Schuchat. The last page of that binder has a chart that I would like to enter into the record and ask unanimous consent to enter into the record. It's PHEMCE's budget report for fiscal year 2016–2020.

Mr. HARPER. Without objection.

[The information appears at the conclusion of the hearing.]

Mrs. BROOKS. A large percentage of the CDC's Strategic National Stockpile budget appears to not go to procuring and updating medical countermeasures for the stockpile, but instead, goes to a category entitled nonprocurement costs. And in an effort to inform the discussion today, committee staff did ask CDC to provide a breakdown for what is in this nonprocurement, but we never got it.

Can you please share with us very briefly, and you might need to supplement with written response, what makes up the non-procurement spending for the Strategic National Stockpile?

Dr. SCHUCHAT. Thanks so much for your question. As you know, the Strategic National Stockpile has an inventory of about \$7 billion. So the annual appropriation is just a piece of that. Most of the dollars that are in the nonprocurement go for sustaining and operating. So that would be the rental space, the security for the warehouses, the staff that work, the salaries for the staff, as well as the clinical expertise that's helping with the guidance on how to use the product.

Mrs. BROOKS. Thank you. Could we get a written breakdown of what that is?

Dr. SCHUCHAT. Absolutely.

Mrs. BROOKS. Because we could not tell what that was.

Dr. SCHUCHAT. That should be on its way to you.

Mrs. BROOKS. Thank you very much.

Dr. Bright, last year, HHS OIG issued a report after conducting five site audits at the various Strategic National Stockpile locations over a 2-year period, and they talked about systemic issues, putting that \$7 billion that was just mentioned into great concern.

So, Dr. Bright, what actions does ASPR plan to take in the transfer that is anticipated October 1 to ensure the Strategic National Stockpile assets will be available in case of public health emergencies?

Mr. BRIGHT. As you probably know, we have several working groups working very closely between CDC and ASPR to evaluate various components of the stockpile transfer. So we are still——

Mrs. BROOKS. Can I interrupt one second? We just heard, in her opening testimony, Dr. Schuchat talk about all the many things CDC does relative to public health and these

emergencies. And so are you going through all of those things to make sure there is coordination? And is that what the working groups are actually doing, figuring out what part CDC is going to maintain and what part ASPR will have? Is that what the working groups are doing?

Mr. BRIGHT. Absolutely. There's five different working groups. They're meeting weekly actually, and some of them have daily communications, to understand the various components, understanding how we maintain and sustain the best science and expertise that's currently in the SNS, understanding how we're building and augmenting the relationship with States and locals to ensure that that is also maintained for a robust SNS enterprise. We're also looking at the contracting and the financing. We're looking at the non-procurement cost as well.

We assure you that we are doing everything we can to make sure that those nonprocurement costs are supporting the SNS and its mission.

Mrs. BROOKS. I have a question with respect to—I understand there have been instances where BARDA—and you mentioned it—had to use Project BioShield funds to procure FDA-approved clinical countermeasures or medical countermeasures, because, for whatever reason, CDC declined to procure those countermeasures for the stockpile.

How does that uncertainty affect BARDA's ability to partner with industry, and is that being addressed in your working groups?

Mr. BRIGHT. That uncertainty is critical. As you know, it's very difficult to make these countermeasures. It's very lengthy, very risky, and the companies put aside other very profitable and successful endeavors to work with us in these areas. That marketplace assurance is absolutely essential to them working with us.

So we realize that, as we've been more successful with our partners and making additional countermeasures, it has created an additional burden on the SNS. We are working with the SNS at the CDC and our internal staff now to make sure that we are able to address those lapses or those gaps in communication or transparency to make sure that we have a successful——

Mrs. BROOKS. Thank you. I'd also like to enter into the record a letter from the Blue Ribbon Study Panel on Biodefense that was sent to Dr. Kadlec with a very detailed seven recommendations to improve our biodefense posture.

Mr. HARPER. Without objection.

[The information appears at the conclusion of the hearing.]

Mrs. BROOKS. And among those was the need to improve the coordination with State and local partners and to address problems that have existed in the past.

Can you tell us how ASPR plans to engage with State and local partners once it assumes control of the stockpile, which is of great concern to State and local partners?

Mr. BRIGHT. I agree that it is an essential part of an effective enterprise, the end-to-end approach, from early detection down to distribution. The State and local and tribal and territorial partners are the front line. They are the ones who are distributing and administering the vaccines and treatments. So we are dedicated to working with them, making sure they have a voice in the structure, in our system, to understand how they need those medical countermeasures and how they need them to be delivered most effectively.

It doesn't do us any good to make new drugs and vaccines if they're not suitable for our frontline workers at the State and local and tribal and territories to deliver and administer those.

Mrs. BROOKS. And so they know how to deliver and administer.

Mr. BRIGHT. Absolutely.

Mrs. BROOKS. Thank you. With that, I yield back. Thank you for your time.

Mr. HARPER. The gentlewoman yields back.

The chair will now recognize the gentlewoman from Florida, Ms. Castor, for 5 minutes.

Ms. CASTOR. Thank you, Mr. Chairman.

Good morning. Last year, Florida recorded 262 known cases of Zika. They were overwhelmingly travel-related cases, but of those known cases, 136 were pregnant women, and three babies were born in Florida with congenital Zika syndrome. Thankfully, those statistics are down substantially from 2015 and 2016, but the threat to young women of childbearing years and families remains very serious.

A study was just published where researchers from the CDC and the Annenberg Public Policy Center determined that most people have let their guard down now, that they're not taking the precautions that they should when it comes to Zika.

So, Dr. Schuchat, now that you have the results of that study and the threat of congenital Zika syndrome remains very serious, what do you plan to do to help keep families informed and make sure they're taking all precautions?

Dr. SCHUCHAT. Thank you. Zika was such a devastating new problem to have. For a mosquito bite to be able to cause birth defects, not something that was on any of our radars, really.

I think you know that, in May, we issued one of our monthly high-visibility reports of vital signs on mosquito and tick-borne diseases, which have really been increasing, trying to get that word out in advance of the mosquito season so people would take these threats seriously.

We have another report that's focused on Zika that will be coming out in about 2 months, really highlighting what have we learned from the, unfortunately, thousands of pregnancies that were complicated by Zika in folks who reside in the 50 States, to show what the followups have been and what has happened to the babies as they develop.

We need to make mosquito protection much easier for individuals and we need to have better tools for countering mosquitoes, in terms of environmentally safe and acceptable tools for them. We have been appreciative of the investments in strengthening our vector control so that there's better surveillance for vector-borne disease, and also better understanding of resistance patterns so we have the right products that can be used.

Ms. CASTOR. And there must be more we can do to communicate to young women and young men, especially now that—I mean, it was very strange that Zika became transferable via sex as well. So——

Dr. SCHUCHAT. Yes. The signs are still up in the airports, but people turn them off. So I think continuing to raise concerns is a challenge when people become complacent. So it's sort of our perpetual challenge in prevention.

Ms. CASTOR. Thank you.

Responding to public health emergencies requires us to have a good understanding of what is happening on the ground in real time. And doctors and nurses and others who work directly with patients are likely to be the first to interact with individuals affected in a public health emergency.

How does CDC gather data from these clinicians to detect emerging illnesses and other threats?

Dr. SCHUCHAT. We have a variety of surveillance systems to try to identify both the known threats and then the unknown or the new unusual clusters. Most important is for there to be a close connection between the clinical community, the doctors and nurses on the front line, and their local and State public health authorities.

The first cases of West Nile virus disease in New York City were detected, there were some animal losses, but it was that link between clinicians and the local health department. So part of our day-to-day everyday public health system is vital for the unknown emerging——

Ms. CASTOR. And CDC has a Laboratory Response Network that plays a vital role in biopreparedness by ensuring that we are able to quickly diagnose public health threats using rapid testing methods known as assays, but I understand that right now, there are no assay kits or rapid tests available for many dangerous pathogens and toxins.

What is going on here, and what are the barriers to developing assays targeting a wide variety of pathogens and toxins?

Dr. SCHUCHAT. Yes. What I would say is that the Laboratory Response Network, or LRN, is a group of 125 hospitals around the— or laboratories around the country that are within a 2-hour drive of 85 percent of all of the population. They are equipped to use validated, standardized assays to detect a variety of conditions.

The CDC has the ability to detect and confirm a longer list of the select agents and dangerous pathogens, and we prioritize which of the detection methods or assays need to be deployed close to where people live, which ones can be deployed and maintained centrally, because it's quite expensive to have the standards high enough to be able to reproduce the results in all of the 125 hospitals.

So while there's 45 select agents, we have assays for nearly all of them. Many of those are managed at the CDC or at Regional Centers of Excellence, while the 125 laboratories can test for the things that we think are the most likely, including things like MERS, where we rolled out an emergency use authorization for a new diagnostic test for that, Ebola, et cetera, the H1N1 initially. So we try to deploy distally the assays for the threats that are the most important to have local ability to detect rapidly.

Mr. BRIGHT. If I can add just a second on that too. That is another area of innovation that BARDA has been focusing on with our industry partners is to drive diagnostics, not only out of centralized labs to augment that centralized laboratory network, but put the diagnostics in the hands of the physicians in the physician's office at point-of-care testing. And even go further now, to drive diagnostics into the home, so people will know earlier when they've been infected with something so they can take responsible action to either get treated sooner when drugs are more effective and also to take activities to reduce the further spread or transmission of that virus. This area is ripe for innovation to augment our national laboratory support system.

Ms. CASTOR. Thank you very much.

Mr. HARPER. The gentlewoman yields back.

The chair now recognizes the gentleman from New York, Mr. Collins, for 5 minutes.

Mr. COLLINS. Thank you, Mr. Chairman.

I want to thank our witnesses and follow up a little bit more on the Laboratory Response Network, Dr. Schuchat. I understand that's been around about 9 years or thereabouts, since I think 1999?

Dr. SCHUCHAT. Yes, since 1999.

Mr. COLLINS. Actually, I've lost 10 years. Twenty years. I deliberately lost those 10 years, by the way.

So I know you mentioned 125 labs here in the country, but this is, from what I understand also, there's international labs. We all know the key to a lot of this is early detection, whether it was Ebola or some other things, SARS, which initially people thought they had the flu, even anthrax. But early detection's the key to jumping on top of this, which means the laboratories that are located outside the country. And I know this is a collaborative effort.

Are you, let's use the word "comfortable," and how is that collaboration between the United States and other countries around the world—as you mentioned, in many cases, these could be in Africa and other places—for the ability to identify these select agents?

Dr. SCHUCHAT. The Laboratory Response Network is in other countries as well, but I would say there's other means, other laboratories that we collaborate with around the world to help have that rapid detection and response. And actually, that's really what the global health security agenda is about, making sure that there are abilities to find, stop, and prevent epidemics wherever they occur, natural or not.

And the international collaboration, I think, is strengthened by the daily links we have in partnership on other threats. As you heard, we're working on Ebola in DRC right now. The Nipah virus detection in India was based on training that CDC had given to the laboratory in India years before so that India could recognize that pathogen themselves without having to take the time to ship the specimens out of the country.

Mr. COLLINS. So, following up on that, what I would call proficiency testing that we do for all of our labs, whether it's on influenza or HIV or any of the STDs, I'm assuming there's also a proficiency testing program related to our LRNs, which is always maybe a little more complicated because the 45 select agents are not nearly as prevalent as influenza. But can you speak to the proficiency program, how often these laboratories are tested, their workers, how their grades are, so that, in fact, we're comfortable that, if there is an outbreak, they're properly identifying it?

Dr. SCHUCHAT. Yes. The proficiency testing and assuring the quality of the laboratory test is vital. That's one of the reasons that we don't have assays for every one of the select agents in each of the LRN labs, because we want to certify that lab for that test and make sure that they maintain their reagents adequately and that everyone who's working on that test is doing it the right way. So we really try to prioritize which assays will be run regularly in every lab, because we do have to make sure that year in and year out, they're getting the accurate results. Otherwise, it makes no sense to run the test.

Mr. COLLINS. Is that done yearly, more than yearly? How often is that done? And does the CDC conduct the proficiency tests themselves or do you use outside agencies like CAP or someone like that?

Dr. SCHUCHAT. Let me get the details on that for the committee in followup, because I don't have all of them myself.

Mr. COLLINS. OK. Thank you. I think that's an important piece. In the remaining time, Admiral Hinton, egg-based versus cell-based vaccines, could you comment? YIs the FDA looking at—as we're moving forward certainly through our influenza season, are you making progress on the cell-based? Are you seeing positive potential there?

Admiral HINTON. Absolutely. And we actually have both. We have the egg-based versus the cell-based vaccines available, and continue to do evaluation and work in that area. But both are available, both are promising.

Mr. COLLINS. Because, there's always been some folks—if anyone else would like to comment on potential problems with the egg-based. Are we seeing positive steps in the other or——

Admiral HINTON. We are seeing positive steps in the other direction. And then as far as the egg-based, I know we run into issues with people having allergens and the like to them and not being able to have them. So having different options there to be able to provide and treat people with is promising and is available.

Mr. HARPER. Dr. Fauci.

Dr. FAUCI. There are other problems with egg-based, which is the reason why we're really trying to get away from egg-based and get more towards more advanced platform technologies.

One of the accidental mismatches that we had in 2016–2017, particularly in Australia, was that the virus was chosen for the vaccine, was put into eggs, and as it mutated in the eggs as it was growing, it mutated so that the virus that came out of the eggs was not the virus that you put into the egg. So we had an accidental mismatch.

That doesn't happen all the time by any means, but the idea of having to grow a virus in a 6-month process is something that we really need to, as I often say, graduate into the 21st century and do it a little bit better with more advanced technologies.

Mr. COLLINS. Thank you for that. Mr. Chair, I yield back.

Mr. HARPER. The chair is going to allow Dr. Bright to finish his response that he wanted to make here quickly.

Mr. BRIGHT. Thank you very much. I'd like to add just a little bit more to that as well. It's very important to understand the need for diversified vaccine production systems for influenza. Influenza's a tricky virus. Eggs have been a reliable vaccine substrate for a number of years. We are working to find ways to not only diversify and augment our cell-based and recombinant-based influenza vaccines, but also to improve egg-based vaccines. It's important not to completely discard a reliable technology without having a modernized technology to replace that. So we are working with each of the manufacturers now to identify ways to make our flu vaccines more effective now while we wait for that universal flu vaccine candidate in the future.

Mr. HARPER. The chair will now recognize the gentleman from California, Mr. Ruiz, for 5 minutes.

Mr. RUIZ. Thank you, Mr. Chairman.

Emerging infectious diseases are a major threat to the health of American citizens and to people around the world. This includes both new diseases that emerge in populations, as well as previously known diseases that re-emerge. In just the past 2 months, for example, we have seen outbreaks of Ebola in the Congo and Nipah in Northern India.

Dr. Schuchat, what steps are we taking to monitor emerging and re-emerging infectious diseases in the developing world, and how are we partnering with international players on this?

Dr. SCHUCHAT. Yes. CDC works closely with dozens of ministries of health around the world, as well as with international partners like the World Health Organization and the World Food Organization to—or the World Animal Health Organization to be able to find, stop, and prevent epidemics.

Mr. RUIZ. Give me an example of how you do that in a very underdeveloped, poor infrastructure nation.

Dr. SCHUCHAT. Right. As you know, in Liberia, they suffered from a devastating outbreak of Ebola in 2014. We have a country office in Liberia that's working closely with them focused on four key areas: strengthening laboratory systems, strengthening surveillance, strengthening emergency operation centers and rapid response, and workforce development through the disease detective program that we call the field epidemiology training program.

That means they can shorten the time to recognition of Ebola or something else and respond capably.

Mr. RUIZ. Thank you.

And in 2014, 2016, the Ebola epidemic killed more than 11,000 people in West Africa, and we know in October 2014, a physician who traveled from West Africa to Dallas in Texas died of Ebola; two others that contracted the Ebola virus survived.

What did we learn from that experience? And what are the changes that you've made because of that?

Dr. SCHUCHAT. There are three key lessons learned. One was that we need every country to have the ability to find, stop, and prevent epidemics, and that's what we call this Global Health Security Agenda.

A second thing was that we need the world organizations, the global organizations, to be able to surge rapidly when a country's capacity is overwhelmed. And that has actually happened effectively in the Democratic Republic of Congo with this Ebola outbreak recently.

And the third thing that we've learned is that infection control is essential; that an issue that is one illness or a couple illnesses can amplify into a very large-scale problem when we don't have adequate infection control. That's important in the United States for antimicrobial resistance, it's important in developing countries for TB, and it's very important for Ebola in SARS.

Mr. RUIZ. This patient and these two other healthcare workers who contracted Ebola, obviously, were in emergency departments, went to emergency departments, were treated in emergency departments. The first line of defense against any emerging infection or outbreak in the United States is going to be the emergency departments and also the first responders.

So what are you doing in terms of the CDC to coordinate to make sure that they are well-equipped? And then I'm going to ask Dr.

Bright that same question.

Dr. SCHUCHAT. Yes. We have a family of efforts to educate and keep up-to-date clinicians that include tens of thousands of clinicians regularly getting updates from us, whether it's through phone calls——

Mr. RUIZ. It's hard for very busy clinicians who work in emergency departments, seeing 20 patients at once to——

Dr. SCHUCHAT. Right. And that's——

Mr. RUIZ. How do you integrate that into their daily practice?

Dr. SCHUCHAT. Yes. The system changes are really important. When I saw a doctor at Emory last week, before I could even talk to anyone, I was asked, Have you traveled out of the country the last 3 weeks? It's actually on their phone line before you make an appointment.

So institutions instituting systemwide checks can help make sure that you don't have problems with human error.

Mr. RUIZ. Dr. Bright?

Mr. BRIGHT. Also, I'd like to highlight that ASPR has spent a lot of time with our hospital protection program and our healthcare coalitions to establish now even a national Ebola training center and education center, so we can train the hospital and first responders.

We now have 178 Ebola assessment hospitals. We have 69 State or jurisdictions designated Ebola treatment centers. We have 10 regional Ebola and other special pathogen treatment—

Mr. RUIZ. Well, I'm an emergency physician. I have to take exams like crazy just to keep my board certifications and my licensing. So I think integrating it as part of their continuing medical education and training would be very essential.

Now, the President's budget—or the administration wants to move the strategic National Stockpile under the ASPR. I'd like to ask Dr. Schuchat what are your competitive advantages and why should I think about even considering keeping it at the CDC?

Dr. SCHUCHAT. What I could say is that there's already been an administrative decision to move the stockpile, and so currently, CDC is working diligently very closely with ASPR to make that transfer as seamless as possible and to mitigate any negative consequences that may have been unintended but that may occur.

I think the critical areas that we are going to focus on are to make sure that State and local support is seamless, and that we work with State and local health departments every day on a variety of things and know them and know where our gaps are and where we need to make progress. We need to make sure that that close relationship continues in a way that doesn't jeopardize the American public.

Second area is the deep scientific expertise that we have across the agency that has contributed to maintenance of the SNS so that when we need clinical guidance for children for anthrax counter-measures, we can get that best advice incorporated. We need to make sure that that continues, but we are well on the way to executing that seamless transition.

Mr. HARPER. The gentleman yields back.

The chair will now recognize the vice chair of the subcommittee, the gentleman from Virginia, Mr. Griffith, for 5 minutes.

Mr. GRIFFITH. Thank you, Mr. Chairman.

After a series of safety lapses in 2014 involving the mishandling of anthrax and smallpox, in response to recommendations from a lab safety expert panel, both the FDA and CDC formed new offices to provide centralized oversight of laboratory safety and science.

Rear Admiral Hinton, I have several questions for you regarding the FDA's Office of Laboratory Science and Safety.

First, how many labs does the FDA have, or oversee?

Admiral HINTON. The FDA has 56 lab facilities.

Mr. GRIFFITH. And do you oversee more than that?

Admiral HINTON. No.

Mr. GRIFFITH. And are you counting everything in a single building, or is that all your labs combined?

Admiral HINTON. Those are the facilities. Within those facilities, there might be a total of 2,800 rooms, with those rooms being described as a space, an office, a closet.

Mr. GRIFFITH. Yes, ma'am.

How many safety inspections of these labs were conducted by the OLSS over the past year?

Admiral HINTON. No inspections have been conducted by OLSS in the past year. However, their labs have been inspected by other entities.

Mr. GRIFFITH. OK. Have there been any laboratory-acquired infections at FDA labs during the past year?

Admiral HINTON. There have been two noted infections within the last year. The staff that had acquired those infections have been observed and the case is closed.

Mr. GRIFFITH. All right. And can you get us the reports on those two incidences, please?

Admiral HINTON. I'll work with my staff to get that to you. Mr. GRIFFITH. Thank you very much.

Likewise, have there been any potential exposures to threat agents at FDA labs during the past year?

Admiral HINTON. Not to my knowledge. No.

Mr. GRIFFITH. All right. At tab 5 in the document binder is a September 2016 letter to the FDA sent the committee indicating its intention to hire 13 permanent full-time employees in the Office of Laboratory Science and Safety, OLSS.

The FDA told the committee this week that OLSS is staffed by only three permanent full-time employees, and three detailees.

Why doesn't the OLSS have the 13 permanent employees that were promised in a September letter of 2016?

Admiral HINTON. Sir, we have put forth the proposal, and as soon as we have the dedicated budget for OLSS, we expect for their current staff to double.

They actually have three permanent staff and three detailed working on this space.

Mr. GRIFFITH. That still only puts you at six as opposed to the 13 that was indicated in 2016.

Admiral HINTON. I agree. And we note that, and then with the approval of the upcoming budget, we will be able to double that and they will have the 13 staff.

Mr. GRIFFITH. The FDA, in the September 2016 letter, committed to this committee, and in July of 2017, published a notice in the Federal Register evaluating the OLSS so the office would directly to the FDA commissioner instead of the chief scientist.

Earlier this week, the FDA told committee staff that the FDA has decided to reorganize again, and that under the new proposal, OLSS will no longer be a direct report to the commissioner and will report to the chief scientist again, just as they did when we had the lapses back in 2014 and contrary to the expert panel's recommendations.

I just would like to know, first, is the chief scientist reporting to you now?

Admiral HINTON. I am the chief scientist. But the Director of OLSS——

Mr. GRIFFITH. Is OLSS reporting to you?

Admiral HINTON. Yes, sir.

Mr. GRIFFITH. And then you report on up the line?

Admiral HINTON. Yes. I do.

Mr. GRIFFITH. So why did FDA reverse course in less than a year and decide to have the OLSS revert back to reporting to the chief scientist?

Admiral HINTON. Well, sir, since that was announced, we have had the chance over the past year to observe and to see where it might be best fit for the alignment within the office.

Within the office of the chief scientist, which reports into the office of the commissioner and to the commissioner, we work on cross cutting cross-scientific issues to include those within laboratory science space.

So we thought that the OLSS would be best aligned there under my direct supervision on their day-to-day activities. The commissioner will be fully apprised of those activities.

Mr. GRIFFITH. Well, and I certainly mean no disrespect to you, but that was the same setup we had when there were problems being reported and we had the expert panel come in and give us recommendations, which FDA agreed to, and now you all are back-tracking.

I understand some different personnel, but it seems to me we're just creating the same problem we had before.

I see my time is up, and I have to yield back. Thank you, Mr. Chairman.

Mr. HARPER. The gentleman yields back.

The chair will now recognize the gentlewoman from California, Ms. Walters, for 5 minutes.

Ms. WALTERS. Thank you, Mr. Chairman.

Dr. Bright and Dr. Schuchat, either through stockpile procurement or through other means, how do your agencies ensure we have sufficient diagnostic test capacity to identify cases of pandemic influenza or other infectious diseases?

Mr. BRIGHT. In terms of development, so we have worked with a number of different manufacturers through the last 10 years to develop diagnostics for influenza, not only laboratory-based diagnostics, but to standardize and update the point-of-care diagnostics for influenza to make sure those are available and in the marketplace for use for pandemic and seasonal influenza detection.

Dr. SCHUCHAT. Yes. And I would say that CDC both develops assays and helps with validation.

You know, a number of years ago, there were quite a few point-of-care tests for influenza detection, and some of them didn't perform as well in the field as we had hoped. So we did quite an effort of validation comparison, shared the data with FDA, and new labeling and improvements in the tests followed from that.

So we will develop tests against pandemic or avian flu and other high-threat concerns, develop them through to emergency use authorization when appropriate, 501(k) when possible.

The 501(k) final process is very labor intensive, very expensive, and there's a limited number of our tests that we are able to put through to that level. But we do work closely with FDA and BARDA on a number of the priority ones.

Ms. WALTERS. Thank you.

Dr. Fauci, you mentioned work by the National Institute of Allergy and Infection Diseases to support research involving diagnostic testing.

From a Homeland Security and public health perspective, multiplex point-of-care technologies are beneficial because they can be used to simultaneously test for multiple infectious disease pathogens with a single blood or urine sample.

Can you tell us about the research NIAID is doing with respect to multiplex point-of-care technologies and how these technologies enhance our ability to detect material threats and infectious diseases?

Dr. FAUCI. Thank you very much for that question.

Yes. We are very heavily involved in that, both with our grantees to get concept to develop into something that's translatable, as well as contract.

There's multiplex, as you mentioned in your statement, is a very important tool of the future now for detecting outbreaks. For example, we have multiplex assays involving a whole series of particular types of viruses. For example, the flaviviruses, which are many of them that we have, particularly in the Western Hemisphere, that we are involved right now in research for the development of a multiplex that would essentially cover all of the associated flaviviruses, and we're doing that with a number of other viruses.

So there's really a very important, I believe, and aggressive ongoing research program at the NIH, mostly through our grantees and contractors.

Ms. WALTERS. OK.

Mr. BRIGHT. If I can jump in, the challenge with the beauty of multiplex assays is that they can do a lot. And the challenge with them is they're very large instruments generally in centralized laboratories in a hospital or a public health laboratory.

The innovation that we're driving today with companies that move multiplex assays to point of care into a physician's office, and even to work with those multiplex technologies to push some of those now out into the home, one of our greatest challenges with our diagnostics for any disease is how long it takes for a patient to get to that system and into the system so they can get a sample drawn and can get a result.

Too much time elapses in that. So we're trying to also use this new technology for multiplex point of care to multiplex point of need into the home to get people earlier notification to empower patients to get treated sooner.

Ms. WALTERS. OK. Thank you.

Rear Admiral Hinton, how many multiplex point-of-care diagnostic tests has the FDA approved for use?

Admiral HINTON. Thank you for your question, ma'am.

Work in this area is progressing well at FDA. We've cleared more than 25 multiplex tests that could be suitable for point-of-care tests.

Ms. WALTERS. OK. And how many others are currently under assessment by the FDA?

Admiral HINTON. I'll have to get back to you. I don't have the exact number.

Ms. WALTERS. OK. Can you describe the range of capabilities that these tests have? You know, how many diseases can one multiplex point-of-care diagnostic test detect?

Admiral HINTON. It can detect many. We can do up to 20—and more than—at one time, which is incredibly important, especially at the point of care so that we can help to easily detect in order to find the best treatment.

Ms. WALTERS. OK. Thank you, and I yield back the balance of my time.

Mr. HARPER. The gentlewoman yields back.

The chair will now recognize the gentleman from Georgia, Mr. Carter, for 5 minutes.

Mr. CARTER. Thank you, Mr. Chairman.

And, Mr. Chairman, I want to echo your comments earlier about what an outstanding panel this is. Thank you all for the very important work that you do. It is extremely important to our country, and we appreciate it very much.

Dr. Bright, I want to start with you. Being, of course, from Georgia, I am somewhat concerned, even still, about the move of the strategic National Stockpile and the management of that from the CDC to ASPR, and I just want to be assured again from you. I've met Dr. Redfield, and I think he's doing a great job. Dr. Schuchat and I have worked together, and I

just can't say enough good things about the CDC and the outstanding work that they do for our country.

And I just want to make sure that they're still going to have the opportunity to stay involved and to be involved in the medical counter-measurement development and everything else that goes along with the SNS.

Mr. BRIGHT. Sir, you have my complete assurance. I echo your comments about the CDC and the great work they are doing. Many people don't know I got my first start in science at the CDC as an ORISE fellow coming from Emory University in Georgia.

I understand and appreciate the great scientific leadership of the CDC and their relationship with state and local and the value of that.

We plan to always include that in our assessment and our programs for the new strategic National Stockpile management.

Mr. CARTER. We talked on it earlier. One of my colleagues had mentioned about the concern particularly that the transfer is not disruptive for the state and local agencies.

What would you suggest that we do to make that as least disruptive as we can?

Mr. BRIGHT. Well, the most important thing is to recognize the value of their voice in the entire process, not just in the transition of the management of the SNS, but an entire end-to-end process of our efficient response to any emergency or public health emergency threat.

So we already have an intentional working group focusing on the state and local and tribal and territory partners and their specific needs and their specific interests to make sure those are encapsulated in our management of the SNS.

Mr. CARTER. Great.

Dr. Schuchat, would you care to comment on that as well? How can we assure that this is not disruptive to our local and state communities?

Dr. SCHUCHAT. I think that change is, by necessity, disruptive, and I think our job is to mitigate that disruption so that people aren't harmed. So I think it's on our radar. We're working really closely together. The Association of State and Territorial Health Officers Board was just at CDC yesterday talking to us about how we can make sure this all goes as well as possible.

Mr. CARTER. And let me ask you—I run the risk of being a little self-serving here—but wouldn't it make sense to look at perhaps just having ASPR colocate down to Atlanta with the CDC? I recognize you're part of HHS, but we have to get out of the mindset that not everybody's got to be in Washington, D.C. We have a big country out here. Dr. Bright, I'm looking at you.

Mr. BRIGHT. We have a big and beautiful country, sir, and I agree with you, and there is no intent to move the strategic National Stockpile from Atlanta to Washington, D.C. There might be one or two individuals who are located in our ASPR office to ensure we have smooth and efficient ongoing communication with the expert staff that is in Atlanta, Georgia.

Mr. CARTER. OK. Well, that might be a good compromise, and we appreciate that very much.

The Ebola crisis that we had, obviously we learned a lot of lessons there, but I was so proud of the public/private partnership between Emory University and the CDC, and all four patients recovered.

And I just wanted to know, will you be using that model in the future for other pandemics and other risks that we might run into? Because we're very proud of the work that was done at Emory University, and I think it's a great example of what we can do in the future.

Dr. Schuchat?

Dr. SCHUCHAT. I would say that CDC benefits tremendously from being located right next to Emory, and there's a really close working relationship. We were fortunate that they such a terrific job in the Ebola—in the care of the patients there.

There's ongoing collaboration and communication and support.

I think ASPR may have a more direct role in the hospitals and the care of such patients, and Dr. Bright might want to comment.

Mr. BRIGHT. I also want to make sure that we capitalize and not lose that expert and lessons learned from Emory University.

As you may know, we stood up a National Ebola Training and Education Center. It's based in Nebraska as collaboration with Emory University, University of Nebraska, and Bellevue. It is an example of one the finest educational centers on Ebola and other epidemic treatments in the world now.

Mr. CARTER. OK. Again, I want to thank all of you for the work that you do. Extremely important, and especially shout out to CDC and the work that they do.

Thank you, and I yield back, Mr. Chairman.

Mr. HARPER. The gentleman yields back.

The chair will now recognize the gentlewoman from California, Ms. Eshoo, for 5 minutes.

Ms. ESHOO. Thank you, Mr. Chairman, for extending the legislative courtesy to me, since I'm not a member of this subcommittee, but I have a great interest in the subject matter, since we're looking to reauthorize PAHPA and all of the listening to what's taken place in this hearing and the superb testimony from each one of you. We've made great progress since the legislation was first written in 2006.

So I'm pleased, but in America, we're never satisfied with exactly where we are. We always want to improve. And so there's been an important pathway of improvement, and I thank each one of you.

I'm very proud of the two women that are here. Rear Admiral Hinton, it's really a source of pride to me to hear you respond to the tough questions that have come your way. To Dr. Schuchat, it's always a pleasure to hear you. Dr. Bright, the partnership with BARDA has been a very important one, and I think that you're taking it to new places.

And to Dr. Fauci, I don't have any questions to ask you. I wish I could canonize you. You are such a gift to our country. You could be in the private sector probably making millions of dollars. You've devoted your entire life to the people of our country, and you make the National Institutes of—the NIH really stand for the National Institutes of Hope. You're a leader in that, and I just revere your record, your leadership, and what you've done and what you continue to do.

To Dr. Bright, how has restoring BARDA as a contracting authority led to increases in the efficiency and the certainty that surrounds the medical countermeasures at research and development? That's my first question.

And my second one is, does your agency interpret your existing authority to allow the stockpile to invest in countermeasures other than those explicitly mentioned in the current statute?

Maybe start with the second question.

Mr. BRIGHT. Thank you very much.

Ms. ESHOO. Do you need any additional authorities?

Mr. BRIGHT. To be more effective, I believe we need to modify some of the authorities that we have to allow us to work more flexibly with our industry.

Ms. ESHOO. So you don't need additional authorities?

Mr. BRIGHT. We don't need additional authorities. I believe we need to modify the authorities that we have.

Ms. ESHOO. What does that mean, modify the authorities?

Mr. BRIGHT. Our other transactional authority, for example, does have limitations on how we can interface with our industry partners and how they might qualify for that type of partnership. So we have a draft of suggested language that might allow us that greater flexibility to do so.

Ms. ESHOO. And have you gotten that to us?

Mr. BRIGHT. If it hasn't been sent to you yet, we will make sure that it is quickly.

Ms. ESHOO. Do BARDA's existing additional authorities promote work on the, and it's been brought up, not only at this subcommittee, but at others, of the antimicrobial resistance and the antibiotic development, or does your agency need additional authorities to engage in that work?

Mr. BRIGHT. We've been working with the authorities we have since 2010 to address antimicrobial resistance.

One area of authority that is lacking, we believe, would be beneficial would be a specific authority for the appropriations for pandemic influenza, because there's a lot of critical work that needs to happen in pandemic——

Ms. ESHOO. Have you gotten that to us?

Mr. BRIGHT. I do not have that authority yet.

Ms. ESHOO. Are you going to make that request of us?

Mr. BRIGHT. I believe that request has been submitted. I hope so.

Ms. ESHOO. There was some mention earlier about how important the advanced—I think you might have raised it in your opening statement, on advanced appropriations. I believe that, because the Senate has different rules on this, that we will meet the standard that needs to be met. That's probably the tidest way for me to say it.

But it is critical, because if you don't have the advanced appropriations at BARDA, then our partners in the private sector are not going to be able to continue the important work that they're doing.

Mr. BRIGHT. That's absolutely correct. They are business partners working in long-term cycles and forward-looking cycles, and the consistency and assurance of that advanced appropriations allows them to have that assurance that we will still be there doing our part so they can plan appropriately as well.

Ms. ESHOO. Thank you very much to each one of you for what you're doing for our country. You're all heroes of mine.

Thank you, Mr. Chairman. Yield back.

Mr. HARPER. The gentlewoman yields back.

The chair will now recognize Ranking Member DeGette for concluding remarks.

Ms. DEGETTE. Thank you very much, Mr. Chairman, for the moment of personal privilege.

I wanted to bring up another issue that I think is a real crisis right now in this country.

I know we have a lot of HHS agency representatives here, and, of course, ASPR is under the purview of HHS.

Yesterday, our ranking member, Frank Pallone, wrote a letter to Secretary Azar about the HHS Office of Refugee Resettlement. And these kids who are being taken from their parents at the border, and then being put under the auspices of this agency, we have real concerns about what's happening to these children. And we have real concerns about their long-term prospects, being taken from their parents.

And, Mr. Chairman, I just wanted to bring this up, because you're going to be getting a request from the minority to have a hearing about this, and we would hope that you would seriously consider this, because we are quite concerned about the human aspects of this situation.

Thank you, and I yield back.

Mr. HARPER. The gentlewoman yields back.

The chair will recognize Dr. Burgess for a concluding remark.

Mr. BURGESS. Well, Mr. Chairman, thank you for the recognition.

I would just point out that this committee, and this subcommittee in particular, has a significant history of oversight on the ORR. I do feel obligated to point out this is not the agency that makes the decision about whether or not a family unit is kept together, but they are obligated to take care of—whether a child arrives unaccompanied or is separated from their family at the DHS facility. But that is the responsibility of, in fact, the Health Subcommittee, and we do take that responsibility very seriously.

In fact, it was our work in July of 2014 that allowed them to acquire an actual physician to be in those facilities to assess those children as they were brought in.

And it was our committee that raised the question shouldn't we at least have some way of contacting the children after they have been placed with a family, at least on a voluntary basis.

So it was our committee that did that work, and that work will continue. I've been in contact with both Secretary Azar and with the gentleman that runs ORR, and I expect to have robust discussions with them going forward, and I yield back.

Ms. DEGETTE. If the gentleman will yield, thank you very much, and I look forward to working with you on this, because it's really a critical issue, and I'm on that subcommittee, too. Thank you.

Mr. HARPER. I want to thank each of you for being here. Great insights and expertise, and I thank you for participating in today's hearing.

I remind Members that they have 10 business days to submit questions for the record, and I ask that the witnesses agree to respond promptly to any such questions.

With that, the subcommittee's adjourned.

[Whereupon, at 10:58 a.m., the subcommittee was adjourned.]

[Material submitted for inclusion in the record follows:]

U.S. HOUSE OF REPRESENTATIVES COMMITTEE ON ENERGY AND COMMERCE

June 13, 2018

TO: Members, Subcommittee on Oversight and Investigations

FROM: Committee Majority Staff

RE: Hearing entitled “The State of U.S. Public Health Biopreparedness: Responding to Biological Attacks, Pandemics, and Emerging Disease Outbreaks.”

The Subcommittee on Oversight and Investigations will hold a hearing on Friday, June 15, 2018, at 9:00 a.m. in 2123 Rayburn House Office Building. The hearing is entitled “The State of U.S. Public Health Bio-preparedness: Responding to Biological Attacks, Pandemics, and Emerging Disease Outbreaks.”

The purpose of this hearing is to follow up on the past biopreparedness oversight issues examined by the Subcommittee, and to receive updates from the agencies on current assessments and strategies. This hearing will also highlight the need to reauthorize the Pandemic and All-Hazards Preparedness Act (PAHPA), which is due to expire at the end of September 2018.⁵

I. Witnesses

Rick A. Bright, Ph.D., Director, Biomedical Advanced Research and Development Authority; Deputy Assistant Secretary, Office of the Assistant Secretary for Preparedness and Response, U.S. Department of Health and Human Services;

- Anne Schuchat, M.D. (RADM, USPHS), Principal Deputy Director, Centers for Disease Control and Prevention, U.S. Department of Health and Human Services;
- Anthony Fauci, M.D., Director, National Institute of Allergy and Infectious Diseases, National Institutes of Health; and
- Denise Hinton (RADM, USPHS), Chief Scientist, U.S. Food and Drug Administration.

II. Background

This section will outline four areas of continuing oversight interest in the area of biopreparedness: biological threats; detection and diagnostics; development and stockpiling of medical countermeasures (MCMs); and science, safety and security of laboratories in the life sciences-biodefense complex.

A. Biological Threats

Biological threats fall into three main categories: natural infectious diseases, synthetic biology/engineered pathogens, and bioterrorism. Synthetic biology could cause harm either

⁵ PAHPA created and expanded programs to enhance the public health system’s capacity to monitor and respond to public health emergencies. The act expanded programs for state and local public health emergency preparedness activities and mandates the use of evidence-based benchmarks and standards to measure levels of preparedness. Ass’n of State and Territorial Health Orgs., *ASTHO Legal Preparedness Series Emergency Authority & Immunity Toolkit -Pandemic and All-Hazards Preparedness Act*, <http://www.astho.org/Programs/Preparedness/Public-Health-Emergency-Law/Emergency-Authority-and-Immunity-Toolkit/Pandemic-and-All-Hazards-Preparedness-Act-Fact-Sheet/>(last visited June 11, 2018).

intentionally (e.g., an engineered pathogen used in a bioterrorist attack) or accidentally (e.g., through the accidental release of dangerous agents from a lab conducting dual use research).⁶

In this century, the nation has witnessed the impacts of naturally occurring outbreaks such as influenza, Ebola, and SARS.⁷ Health authorities are currently monitoring other potential emerging infectious diseases that could cause a pandemic, such as the H7N9 influenza strain circulating in China.⁸ Further, as recently noted by Department of Health and Human Services (HHS) Assistant Secretary for Preparedness and Response (ASPR) Robert Kadlec, “[t]errorist organizations such as ISIS and al-Qaida remain determined to attack; further ISIS has demonstrated no compunction about using chemical and other unconventional weapons in attacks overseas. State actors have already threatened our homeland with nuclear weapons and have shown the means to employ both chemical and biological weapons.”⁹

The Subcommittee explored the growing nature of these biological threats and the need for an elevated response at a hearing held on February 12, 2016.¹⁰

An attachment to this memorandum provided by the National Institute of Allergy and Infectious Diseases (NIAID) shows examples of emerging and re-emerging infectious diseases as of June 2018.

B. Detection and Diagnostics

Laboratory Response Network

The Centers for Disease Control and Prevention (CDC) Laboratory Response Network (LRN) is a network of 134 local, state and federal laboratories that can provide the laboratory infrastructure and capacity to quickly respond to public health emergencies, and incidents of biological and chemical terrorism. The network, established in 1999 and overseen by the CDC, enables rapid detection of and response to emerging infectious diseases such as Zika, Ebola and influenza, as well as select agents and toxins. All 50 states have at least one member laboratory and 85 percent of the U.S. population lives within a two-hour drive of an LRN lab.

The ability of the LRN to respond to quickly unfolding emergencies is essential and, as such, the network was designed to deploy rapid detection technology and laboratory tests (known as assays) to quickly test suspicious materials and detect the presence of biological or chemical agents in the event of a bioterrorism attack.

In August 2016, the Committee launched a bipartisan investigation about the current capabilities of the CDC LRN, and two additional information request letters followed on

⁹ *Id.*

¹⁰ See *Outbreaks, Attacks, and Accidents: Combating Biological Threats Before the Subcomm. on Oversight and Investigations of the H. Comm on Energy and Commerce*, 114th Cong. (2016) Serial No. 114-117.

October 26, 2016, and February 28, 2017.¹¹ These letters requested information regarding the LRN's lab capacity, funding levels, and laboratory test development.

In response to questions about funding for the network, the CDC provided documentation indicating that spending decreased over the last decade. The LRN's expenditures have gradually decreased from \$15 million in 2007 to \$9 million in 2016. Expenditures for the LRN totaled \$116.2 million during that 10-year period.¹² The CDC has also at times received funding from other federal agencies to help support network activities. The Department of Homeland Security's Science and Technology Directorate, Department of Defense's Defense Threat Reduction Agency and its Joint Program Executive Office, and the Department of Health and Human Services' Office of the Assistant Secretary for Preparedness and Response (ASPR) and Biomedical Research and Development Authority (BARDA) have each provided funding for LRN support over the last 10 years. Funding has varied year-to-year by agency, but the total amount the four agencies have provided to the LRN since Fiscal Year 2008 is \$21.5 million.¹³

In response to questions on lab test development, the CDC provided information about the process by which it selects and develops new assays the LRN can use to detect for biological agents, toxins and emerging infectious diseases. The CDC has indicated that the Food and Drug Administration (FDA) has approved 510(k) clearances for four assays and issued emergency use authorization for another six assays.¹⁴ Out of a total of 45 select agents affecting humans on the current select agents and toxin list,¹⁵ the CDC LRN has assays cleared by FDA under the 510(k) process for three, after nearly 20 years of the LRN program and more than \$135 million in funding during the last decade.¹⁶

Most recently, the CDC arranged for the evaluation and deployment of a Department of Defense Ebola Zaire assay by the LRN amid the 2014 Ebola epidemic in West Africa. After the 2015 Zika outbreak in Brazil, the CDC also began development of an LRN diagnostic for the Zika virus.¹⁷

Biosurveillance

Two areas of biosurveillance of interest to the Subcommittee have been BioWatch and multiplex point-of-care technologies (MPOCTs). BioWatch is an early warning system designed to detect a large-scale, covert attack that releases anthrax or other agents of bioterrorism into the air. Overseen by the Department of Homeland Security (DHS), the BioWatch program involves a system of aerosol collectors deployed in more than 30 cities, as well as laboratory facilities and personnel to analyze samples from these collectors. This program relies heavily on CDC, and the state and local public health laboratories that are members of the CDC LRN. The program aims to reduce the time required to recognize and characterize potentially catastrophic aerosolized attacks by monitoring for the presence of certain biological agents considered to pose high risk for an aerosolized attack. A committee investigation and a U.S. Government Accountability Office (GAO) report found that DHS lacked reliable information about BioWatch's technical capabilities to detect a biological attack and therefore lacks the basis for informed cost-benefit decisions about upgrades to the system.¹⁸ DHS continues to work on ways to upgrade the BioWatch system.

MPOCTs are technologies that can simultaneously test for more than one type of human infectious disease pathogen from a single patient sample (such as blood, urine, or sputum) in one run at or near the site of a patient. MPOCTs can enable rapid testing while the patient is at the doctor's office, clinic, or other testing location, including the home. From a homeland security and public health perspective, MPOCTs are of interest as an early detection tool, and can help assess the potential spread and effect of the disease in the case of dangerous pathogens. At the Committee's request, the GAO conducted a technical assessment of MPOCTs.¹⁹ The GAO found that MPOCTs have a range of performance characteristics that describe, among other things, the ability of the technology to correctly identify the presence or absence of a pathogen. Developers identified several technical challenges to developing multiplex assays that can slow MPOCT development and raise costs. GAO also identified potential benefits of MPOCTs included improved patient health care and management, more appropriate use of antibiotics, improved ability to limit the spread of disease, and health care cost savings.

C. Development and Stockpiling of Medical Countermeasures

Public Health Emergency Medical Countermeasures Enterprise

In 2006, HHS established the Public Health Emergency Medical Countermeasures Enterprise (PHEMCE) to coordinate federal efforts to prepare for, and respond to, public health emergencies from a MCM perspective.²⁰

¹⁸ See *Continuing Concerns Over BioWatch and the Surveillance of Bioterrorism Before the Subcom. on Oversight and Investigations of the H. Comm. on Energy and Commerce* 113th Cong. (2013) Serial No. 113-56; U.S. Gov't Accountability Office, *Biosurveillance: DHS Should Not Pursue BioWatch Upgrades or Enhancements Until System Capabilities Are Established*, GAO-16-99 (Oct. 2015) available at <https://www.gao.gov/assets/680/673309.pdf>.

¹⁹ U.S. Gov't Accountability Office, *Medical Devices: Capabilities and challenges of technologies to enable rapid diagnoses of infectious diseases*, GAO-17-347 (Aug. 2017) available at <https://www.gao.gov/products/GAO-17-347>.

²⁰ See 71 C.F.R. § 129 (2006) and U.S. Dep't of Health & Human Services, Assistant Sec'y for Preparedness and Response, *Public Health Emergency Medical Countermeasures Enterprise*, <https://www.phe.gov/Preparedness/mcm/phemce/Pages/default.aspx> (last visited June 11, 2018).

Pursuant to the 2013 Pandemic and All-Hazards Preparedness Reauthorization Act, the PHEMCE is led by the ASPR and is comprised of senior leadership from the CDC, the NIAID at the National Institutes of Health (NIH), the FDA, the Department of Defense (DoD), the DHS, the Department of Veteran's Affairs (VA) and the Department of Agriculture (USDA).²¹

The PHEMCE's mission components include:²²

- Requirements Setting: The PHEMCE is responsible for establishing requirements for MCMs based on factors such as threat and risk assessments, which are principally conducted by the DHS.
- Early Stage Research: The NIH is the lead federal PHEMCE agency for conducting and facilitating research into areas of public health concerns, which could ultimately lead to the development of MCMs to diagnose, treat, and prevent a wide-range of public health threats.
- Advanced Development/Manufacturing: The Biomedical Advanced Research and Development Authority (BARDA), within HHS' ASPR, develops MCMs for emerging public health threats and partners with industry to accelerate development and increase MCM manufacturing capacity. In the past decade, BARDA's efforts, supported by industry and government partnerships, have resulted in 35 FDA approvals for 31 unique MCMs for threats to the public health.²³ BARDA has also supported the development of 27 MCMs against threats that have been identified by the DHS, through Project BioShield, as being national security threats.²⁴
- Regulatory Science Management: The PHEMCE endeavors to ensure MCMs are safe and effective, which is generally the responsibility of the FDA.
- Procurement/Inventory Management/Stockpiling: The PHEMCE oversees the procurement and management of MCMs to respond to public health threats. Currently, the CDC and BARDA are the lead PHEMCE agencies for this mission component.
- Response Planning, Policy, Guidance and Communication: The PHEMCE, led by CDC and ASPR, coordinates federal medical response and communication strategies when faced with a public health emergency.
- Deployment/Distribution/Dispensing/Administration: The CDC and ASPR engage and coordinate with state and local partners to facilitate the distribution of MCMs and administration of other medical assets in times of public health emergencies.
- Monitoring/Evaluation/Assessment: The CDC and FDA are the principal PHEMCE agencies for monitoring the safety and performance of MCMs that have been deployed in response to public health emergencies response.

²³ Kadlec, *supra* note 3.

²⁴ *Id.*

Concerns have been raised about the length of time it takes to classify a hazardous pathogen as a material threat and then approve the development of medical countermeasures. According to ASPR, it can take upwards of two years for the DHS to designate a pathogen as a material threat.²⁵ For example, carfentanil, a highly potent form of fentanyl, was known as a weapon of mass destruction after Russian forces used it in the Moscow theatre against Chechen terrorists in 2002,²⁶ but pharmaceutical-based agents, such as fentanyl, were only recently added as a material threat. ASPR would like to reduce the time it takes for the DHS to designate a material threat to 90-days or less.²⁷ After a pathogen is classified as a material threat, PHEMCE can approve the development of MCMs for a material threat. ASPR is currently considering other steps that could reduce the timeframe to approve countermeasure development while still maintaining an adequate level of input from all PHEMCE partners and experts, and hopes to devise a plan to reduce the MCM development timeframe by year's end.²⁸

Strategic National Stockpile

The CDC is the primary federal agency responsible for public health surveillance, epidemiologic investigations, and public health communications. The CDC is also currently responsible for managing the Strategic National Stockpile (SNS), though the President's Fiscal Year (FY) 2019 Budget Request transfers SNS management authority from the CDC to HHS' ASPR.²⁹

The SNS is a federal repository of MCMs such as vaccines, antibiotics, and other medical supplies that are to be used in public health emergencies.³⁰ For FY 2018, the SNS received a total of \$610 million, including supplemental funding included in the omnibus spending bill passed earlier this year. Since FY 1999, the federal government has appropriated more than \$9.15 billion to the SNS, with annual SNS funding levels significantly increasing in the years following the September 11, 2001, terror attacks and 2001 anthrax attacks.³¹

Through coordination with the PHEMCE, CDC's current responsibilities regarding the SNS include MCM procurement, shelf life analysis, and MCM replenishment. In addition, the CDC, through its Office of Public Health Preparedness and Response (OPHPR), is also responsible for the delivery of MCMs to areas that have been affected by public health emergencies. OPHPR also provides training to state and local medical personnel and public health officials on how to properly receive and distribute MCMs from the SNS in the case of

a public health emergency. In 2017, OPHPR provided such training to more than 3,700 state and local personnel and led a total of 12 medical emergency simulation exercises.³²

Source: Centers for Disease Control and Prevention.

Over the last few years, independent audits have raised concerns over CDC’s logistical management of the SNS. In June 2017, HHS’ Office of Inspector General (OIG) issued a report which called into question the readiness of the CDC to effectively deploy SNS resources during a public health emergency.³³ In its review, OIG identified “systemic issues [that] could put at risk approximately \$7 billion of Stockpile inventory and negatively affect Stockpile readiness during a national emergency.”³⁴ The OIG’s conclusion was based on a review of findings from each of five SNS site audits that covered FYs 2013 and 2014, and additional information related to the value of the SNS, security, and funding.

Questions have also been raised about the SNS Division of State and Local Readiness (DSLRL), which oversees expenditures of about \$8.6 million. The DSLRL initiatives are meant to ensure that local partners have the resources and training in place to distribute and properly use products from the SNS in the event they need to be deployed. ASPR, however, has identified concerns with state and local partners’ current state of readiness, specifically regarding “last mile” distribution and how quickly partners are able to distribute products on the ground after receipt from SNS.³⁵ Among the concerns highlighted by ASPR is that state and local partners currently do not know what products are in the SNS and therefore do not know how to properly deploy the products.³⁶ To improve state and local readiness, ASPR intends to bolster education and training programs so local partners and first responders have familiarity with SNS products. ASPR also intends to review assessment tools used to rank state and local partners’ readiness status and to design an array of distribution models that could be implemented by local entities to improve their response plans.³⁷

Other issues raised regarding the CDC’s management of the SNS include instances in which the CDC failed to fund the procurement of an MCM for the SNS after the MCM’s

³⁶ *Id.*

³⁷ *Id.*

development and FDA approval.³⁸ For example, there have been instances where BARDA has had to use Project BioShield funding to procure MCMs that have been FDA-approved but were not ultimately purchased by the SNS. The reason for this was due to the fact that the government has to not only ensure that the specific MCMs remain available, but also must sustain a company since they are developing MCMs that do not have a traditional commercial market. Some of the MCMs that have been produced in this manner include: anthrax vaccine adsorbed; axibacumab; and obiltoxaximab.³⁹

Recently, members of the Blue Ribbon Study Panel on Biodefense wrote to Dr. Robert Kadlec, HHS ASPR, with a number recommendations to enhance the United States' MCM infrastructure. Included among the Panel's recommendations were proposed SNS management reforms, which, according to the Panel, were precipitated by the CDC's inadequate management of the SNS.⁴⁰

Pursuant to the President's FY 2019 budget, the transfer of the SNS from the CDC to the ASPR will be effective October 1, 2018.⁴¹ According to HHS, the benefits of moving the SNS to ASPR include that: (1) a unified command for the SNS as the reorganization will vest the MCM production and stockpiling responsibilities with a single agency; (2) ASPR's mission is more targeted than that of the CDC's, enabling it to be a better advocate for the SNS; and (3) ASPR has established relationships with state/local emergency responders, who would play a critical role in a SNS deployment.⁴²

National Pre-Pandemic Influenza Stockpile

In November 2005, the White House Homeland Security Council issued the *National Strategy for Pandemic Influenza*, designating HHS as the department to lead the nation's medical response to pandemic influenza.⁴³ According to the CDC, a pandemic influenza occurs when a new influenza A virus emerges, usually originating in animals, that is able to easily spread from person to person due to lack of effective treatments and acquired immunity.⁴⁴ The *National Strategy* also emphasized the need to ensure that the nation had an adequate MCM production capacity and stockpile to respond to potentially pandemic strains of influenza.⁴⁵ The Homeland Security Council reiterated the importance of having a pre-pandemic MCM stockpile in its *National Strategy Implementation Plan*, which was released in May 2006, categorizing the pandemic threat as a national security issue.⁴⁶

BARDA, which was established by the Pandemic and All-Hazards Preparedness Act, is responsible for the procurement and management of the nation's pre-pandemic influenza stockpile as well as the development of influenza MCMs. BARDA is also tasked with accelerating the development and procurement of MCMs related to chemical, biological, radiological, and nuclear threats as well as threats related to emerging infectious diseases.⁴⁷

In June 2017, and at the Committee's urging,⁴⁸ HHS issued an update to its *Pandemic Influenza Plan*, which was initially published in 2005 and had been last updated in 2009.⁴⁹ In the 2017 update, HHS stated that the national pre-pandemic influenza stockpile "satisfies requirements for vaccine and adjuvants to address influenza viruses that are assessed to be the highest risk for human infection."⁵⁰ BARDA, in collaboration with other HHS agencies, utilizes CDC's Influenza Risk Assessment Tool (IRAT) to assess pandemic risks that are associated with emerging novel influenza viruses and make determinations regarding a potential update to the pre-pandemic stockpile or the development of new vaccine candidates.⁵¹

CARB-X

CARB-X is a non-profit public-private partnership dedicated to accelerating antibacterial research to tackle the global rising threat of drug-resistant bacteria.⁵² With more than \$500 million to invest between 2016 and 2021, CARB-X funds the research and development of new antibiotics, vaccines, rapid diagnostics and other life-saving products to tackle the global threat of drug-resistant bacteria. CARB-X was created in response to the U.S. government's 2015 Combating Antibiotic Resistant Bacteria (CARB) initiative, and the United Kingdom's government's call in 2016 for concerted global effort to address the growing drug-resistance public health crisis. Launched on July 28, 2016, CARB-X is a cooperative effort between BARDA and the NIAID. CARB-X is funded by BARDA and Wellcome Trust, the world's largest medical charity which is based in the U.K.

D. Science, Safety and Security of Laboratories in the Life Sciences-Biodefense Complex

Currently, there are about 1,200 high-containment laboratories in the U.S. conducting research on diagnostics and cures for highly dangerous pathogens. For more than a decade, the Subcommittee has held hearings and conducted investigations related to the Federal Select Agent Program, including on the safe handling of federal select agents and other dangerous pathogens.

Federal Select Agent Program

The Federal Select Agent Program regulates the possession, use, and transfer of biological select agents and toxins to ensure laboratory research conducted on the materials is done in a safe and secure manner. Sixty-six select agents and toxins that could potentially be used in bioterrorist attacks – including anthrax, smallpox, and plague – are currently regulated through the program. Managed jointly by HHS and the USDA, the program provides oversight of more than 275 entities that have registered through the program in order to conduct research on the hazardous pathogens.⁵³

The Federal Select Agent Program was established in 1996 through the passage of the Antiterrorism and Effective Death Penalty Act. The law, passed in the aftermath of the Oklahoma City bombing, required HHS to identify a list biological agents and toxins that could threaten public health and safety and establish regulations regarding the transfer of those agents. The September 11, 2001, terrorist attacks and the 2001 anthrax mailings led to increased concern about the threat of bioterrorism attacks, and additional restrictions which banned certain individuals from transporting or receiving select agents were included in the USA Patriot Act of 2001.⁵⁴ Congress expanded the program through the passage of the Public Health Security and Bioterrorism Preparedness and Response Act of 2002 to include regulation of the transfer and the use and possession of select agents and increased safeguards and security requirements.

Concerns raised by the mishandling of dangerous pathogens prompted the Committee to request an assessment of the select agent program by the GAO. In response to the Committee's request, the GAO reviewed oversight procedures of the select agent program and issued a report in October 2017 that highlighted deficiencies in the program's capabilities.⁵⁵ The report raised concerns about potential conflicts of interest as the select agent program is not independent from all the laboratories it oversees. The report also noted that the program has historically focused more on security and preventing thefts of select agents and toxins than on biological safety issues within the labs using the pathogens for research. The Subcommittee, which has held multiple hearings on the select agent program and safety lapses at federal labs, questioned USDA and CDC officials about the GAO report's conclusions and recommendations at a November 2, 2017, hearing.⁵⁶

Prioritizing Lab Science and Safety

Following the 2014 incidents involving anthrax mishandling at the CDC and the smallpox discovered in storage for an FDA lab on the NIH campus, federal efforts intensified to improve the management of government labs. In particular, an external scientific working group recommended improvements to the CDC and FDA for overhauling their lab safety programs.

This included the recommendation that a program director would be a single point of accountability and would have a direct reporting relationship to the head of the agency. When

Comm. on Energy and Commerce 115th Cong.* (2017) available at <https://docs.house.gov/meetings/IF/IF02/20171102/106574/HHRG-115-IF02-Transcript-20171102.pdf>.

Stephan S. Monroe, the CDC's Associate Director for Laboratory Science and Safety (ADLSS), testified before the Subcommittee in April 2016, he said the formation of the director position was "the most fundamental change implemented in the wake of the 2014 incidents."⁵⁷ Further, Dr. Monroe noted that the fact that the ADLSS reported directly to the CDC director provided "high-level oversight and coordination of critical laboratory policies and operations" across all CDC campuses.

In response to the 2014 safety lapses,⁵⁸ the FDA's Office of Laboratory Science and Safety (OLSS) was formed in order to provide oversight and to improve security and safety across all divisions of FDA. The formation of the office was announced in 2016 as a means to consolidate oversight responsibilities and standard policies for all FDA laboratories. In 2017, the FDA issued a strategic plan outlining the goals of the new office.

According to the OLSS strategic plan, the office's mission is to:

- Ensure FDA's laboratories and workplaces are operated in a safe and secure manner to protect employees, the surrounding communities, and the environment;
- Research and disseminate innovative ideas and validated methods for safe and secure laboratory practices;
- Support high-quality (i.e., accurate, reliable, and timely) FDA laboratory results; and
- Promote a culture of shared responsibility and safety.⁵⁹

Just as the ADLSS was organized to directly report to the CDC Director, the OLSS was also envisioned to directly report to the FDA Commissioner. A reorganization issued by the FDA in 2017 made the OLSS a direct report to the FDA Commissioner.⁶⁰ However, the FDA now plans to have the OLSS report to the Office of the Chief Scientist instead of directly to the Commissioner.⁶¹

In addition, the budget and staffing for the OLSS have not been consistent. In 2016, the FDA informed the Committee that the office's budget for FY 2017 was \$5.2 million and that it would support 13 full time employees.⁶² FDA officials subsequently told Committee staff that the FY 2017 budget for OLSS was \$9 million, but that funding levels would support not just OLSS operations (including staff and contractor support) but also the Employee Safety

and Environmental Management staff that were transferred to OLSS.⁶³ The FDA later informed the Committee that no permanent full-time employees (FTE) were hired by OLSS in FY 2017, rather the office recruited 19 individuals through temporary detail assignments and contract support.⁶⁴ In a briefing with Committee staff, the FDA confirmed that the office's FY 2018 budget is \$5.6 million and the FY 2019 budget is \$6 million.⁶⁵ The office currently employs three FTEs and three contractors. At this time, FDA has not reported the total number of FDA laboratories to the Committee staff. FDA has not yet reported to the Committee the number of audits that OLSS has conducted.

By contrast, the CDC's ADLSS office's FY 2016 budget was \$14.5 million and supported 34 FTEs.⁶⁶ As of this month, the office had 43 FTEs with three slots vacant and oversaw audits of laboratories used by 239 teams of scientists.⁶⁷ The CDC recently reported to Committee staff that it had submitted a proposed reorganization to the Department that would eliminate the Associate Director's direct reporting relationship to the Director, and instead would report to a Deputy Director.⁶⁸

III. Issues

The following issues may be examined at the hearing:

- How timely are the PHEMCE decisions regarding biological threats being made? Can the timeliness of these decisions be improved?
- How can the number of FDA-approved assays for threat agents be increased?
- Is there adequate oversight to ensure the efficacy of MCMs in the SNS and the prepandemic vaccine stockpile?
- Are U.S. public health agencies implementing recommendations to improve laboratory science and safety?

BLUE RIBBON STUDY PANEL ON BIODEFENSE

May 15, 2018

The Honorable Robert Kadlec
Assistant Secretary for Preparedness and Response
U.S. Department of Health and Human Services
200 Independence Ave., SW
Washington, DC 20201
Re: Transforming medical countermeasure technology and partnerships

Dear Dr. Robert Kadlec:

The Blue Ribbon Study Panel on Biodefense recently moderated two roundtables to identify ways to overcome some of the most vexing medical countermeasure (MCM) technology, business, and policy challenges across the biological threat domain. Private sector pharmaceutical, scientific, academic, and governmental affairs representatives attended and were joined at the second meeting by federal officials from the Department of Agriculture (USDA), Department of Defense (DOD), Department of Health and Human Services (HHS), and the White House.

The MCM assets now available to civilians and to military personnel have grown substantially in the last decade. The partnerships needed to continue to build these assets to meet persistent and advancing biological threats, however, are now at considerable risk. Real and perceived under investment, unsustained investment, process uncertainty, and strategic disparity undermine what must be a vibrant enterprise. We maintain that advancing the national MCM infrastructure needed for research, development, and procurement will reduce the risk associated with biological warfare, bioterrorism, emerging infectious diseases, and biological accidents. We urge you to demonstrate your commitment to this core national security function by advancing the following recommendations.

1. Integrate animal health into the national security approach to medical countermeasures. The gross inequality between human and animal funding levels and the segregation of research between the two sectors constitute a national security liability. Many material threats, select agents, and emerging infectious diseases are human diseases with veterinary counterparts, some of which regularly cause outbreaks elsewhere in the world in livestock and wildlife. Yet conversations about the protection of human health by controlling emerging infectious diseases in animal hosts have been extremely limited, and the authority of animal health agencies to regulate has been based on animal health, not public health.

- a) *Establish a framework for combatting emerging infectious diseases.* Most emerging infectious diseases in people originate in animals. No MCM were ready when the largest Ebola outbreak the world had ever seen -likely caused by a spillover from bats to humans-occurred. In the preceding years, the government had not sufficiently determined what to fund with its limited resources. At present, HHS prioritizes efforts to address biological threat agents via Department of Homeland Security material threat determinations (MTDs), but the U.S. government has not instituted

and budgeted for an analogous process for emerging infectious diseases. In accordance with Blue Ribbon Study Panel Recommendation 7c (*A National Blueprint for Biodefense*, 2015), HHS, in coordination with DOD and USDA, should create a similar prioritization framework for emerging infectious disease threats. This framework should address pathogens and pathogen families with the potential to cause a catastrophic public health emergency and include agents known to infect wildlife and domestic animals. It should drive funding for MCM development and other areas (e.g., biosurveillance, response planning) and engage and motivate the private sector to develop and manufacture MCM. Funders must establish a vision for an emerging infectious disease MCM enterprise, define what constitutes successful emerging infectious disease MCM, and communicate this vision along with specific product requirements to industry partners.

- b) *Make USDA part of the Public Health Emergency Medical Countermeasures Enterprise (PHEMCE)*: BARDA was envisioned to be part of- not the entire- MCM enterprise. USDA should also participate in PHEMCE. Many diseases that could necessitate USDA MCM acquisitions are the same for DOD and HHS. USDA also has lessons to share about how it works with industry to develop effective MCM for production animals, a market in which the cost must be low and efficacy must be high. Some veterinary companies are already using platforms to develop their animal products, and the veterinary development timeline is much shorter. This means animal health pharmaceutical companies get products to market earlier. These companies also possess extensive experience in areas like animal models and manufacturability that can help inform human MCM endeavors. These experiences are relevant and should not be ignored.
- c) *Require animal disease risk assessment*. USDA should develop a risk assessment for animal diseases and work with HHS to assess the risk of diseases with zoonotic potential. USDA should assess the ability of the National Veterinary Stockpile to deploy sufficient MCM to combat high-consequence animal diseases within 24 hours of request. USDA should also use these risk assessments to prioritize the pathogens identified on the USDA *High-Consequence Foreign Animal Diseases and Pests* list. USDA should use the findings to inform its budget request; drive federal priorities for MCM innovation; and incentivize public-private partnerships to develop, transition, approve, license, and procure these products.

2. Reduce market and process uncertainty at BARDA. Variability and lack of certainty are two of the foremost hurdles to expanding industry participation in MCM advanced development and manufacturing. Indeed, these hurdles may prove so significant for some companies, even those that have successfully delivered MCM, that they may exit the market entirely. Although all biopharmaceutical ventures carry risk, larger companies can manage this risk through a balanced portfolio of projects, the most successful of which can yield a high return on investment. Pervasive market uncertainty in the far less profitable MCM enterprise makes business endeavors unattractive and unsustainable.

- a) *Create fiscal certainty*. In order to develop national security MCM, industry partners forego potential profit margins orders of magnitude higher than for commercial products. These companies need certainty in procurement to convince them and their investors that engaging in MCM development makes reasonable business sense. The annual appropriations process for advanced development and procurement, and

dependency on emergency supplemental appropriations for unanticipated threats, make doing business with companies that base their operations on multi-year outlooks and planning unsustainable. In accordance with Blue Ribbon Study Panel Recommendation 28b (*A National Blueprint for Biodefense*, 2015),

Congress must reinstate the advanced appropriation for Project BioShield for ten years at a minimum of \$7.1 billion. Additionally, in accordance with Blue Ribbon Study Panel Recommendation 28c, Congress and the HHS Assistant Secretary for Preparedness and Response (ASPR) should address prioritization and the need for guaranteed, sustained funding for pandemic influenza preparedness. The appropriation levels must be tied to rigorously established MCM requirements based on risk analysis.

- b. *Create process certainty:* In the last several years, the f IHS Biomedical Advanced Research and Development Authority (BARDA) noticeably shifted away from process and partnership toward product. Prioritizing products over partnerships has damaged partnerships and preparedness. The rules governing BARDA and DOD processes for advanced development and manufacturing should be defined with industry partners up front and with far greater clarity and commitment. Companies need to understand when and how much of their proposed product the government will procure, as the frequent moving of goalposts throughout development and procurement creates an untenable business environment. For projects in which the government is not interested, federal public health security leaders need to relay that quickly (i.e., white papers should be reviewed and comment provided within 45 days). The BARDA process at this stage of review should be more like that of the Defense Advanced Research Projects Agency (DARPA), for which program managers, not contracting officers, are the central deciding figures.

3. Accelerate platform technologies. One way to create MCM quickly, safely, and effectively for unpredictable emerging infectious diseases and outbreaks is to develop a suite of platform technologies. Generally, platform technologies rely upon a common manufacturing process backbone that uses a standard process to insert foreign genes. By relying upon a well-established manufacturing process and customization through standardized processes, platform technologies can reduce the risk associated with development. These production platforms may be based on, but not limited to, RNA expression systems; DNA cloning vectors; various virus, plant, or bacterial expression vectors; and viral-vectored vaccines. With targeted government and industry investments, these technologies could come to fruition within three to four years, especially for vaccines and diagnostics. To mature the technology, however, the government must mature the way it invests in the technology and ensure that partnership and business plans accompany technical plans for leveraging any platform capability. There is presently no business model in place that addresses how the government can work with industry to develop MCM platforms. At a minimum, elements of certification, expedited review, and the role of the HHS Centers for Innovation in Advanced Development and Manufacturing must be addressed.

- a. *Certify platforms:* The Food and Drug Administration (FDA) approves products, not platforms. FDA, in consultation with DOD, BARDA, and other PHEMCE partners, should establish an MCM platform certification process. A regulatory construct that allows for the consideration of a company's novel platform as a basis for future MCM products would serve as an industry incentive. Its establishment would

effectively reduce the risk of future product development using that platform. Determining what constitutes a platform will be difficult, but the definition should include a regularized chemistry, manufacturing, and controls (CMC) process and standardized general release criteria. The USDA Center for Veterinary Biologics policy, "Licensing Guidelines for Production Platform-Based, Non-Replicating, Nonviable Products," allows for rapid swapping of closely related immunogenic determinants, and could provide a starting point from which FDA could build a platform certification process for human products.

- b. *Priority review platforms:* The platform certification process described above is likely to be extensive and should result in a thorough FDA understanding of the platform technology (e.g., CMC, clinical experience). This advanced understanding will enable subsequent review by the FDA under the expedited Priority Review process of other products based upon that certified platform. FDA commitment to the accelerated approval times associated with Priority Review for subsequent products utilizing a certified platform would provide significant incentive for industry to utilize appropriate platform technologies.
- c. *Leverage CIADMs:* The HHS CIADMs and the DOD MCM Advanced Development and Manufacturing facility (ADM) were envisioned to make such platform-based products a reality. They could enable advanced development and manufacturing of platform technologies if aggressively integrated into the product development process. They should become places where companies want to go to advance their promising technologies. They should shrink development schedules and address significant business difficulties. At present, two major challenges prevent this: small companies are concerned about protecting their intellectual property when handed over to a privately owned ADM with its own MCM interests, and large companies are concerned about risks to their commercial business during regulatory review. The Salk Institute, a private nonprofit organization, was essentially the forerunner of what we think of as an ADM today, and BARDA should consider Salk's example as it revisits the business model for these kinds of facilities. DOD and BARDA should undertake planning for CIADM reconfiguration immediately. Planning should include industry and all federal agencies with MCM responsibility. Considerable thought must be given to contracting reform (discussed below) as the Federal Acquisition Regulation (FAR)-based, cost- reimbursable contract system in place does not work. An independent assessment (outside of DOD and HHS) of the existing CIADM model is needed to support this reconfiguration. This planning must consider the role of the USDA and its industry partners in using the CIADMs to enable mutually beneficial technologies and to keep the facilities in use.

4. Reform FDA process to develop products faster. We can get closer to on-demand MCM in just a few years and investments to improve production cycling by days or weeks are possible. These kinds of advances, however, will not provide the same near-term relief that FDA could achieved on release testing. Investment in enabling technologies must go, therefore, hand in hand with reform of regulatory process. FDA needs to be part of the advanced development process early on, describing what it wants to see in a product or an investigational new drug. Advances in the speed with which products are marketed should not compromise the FDA's high safety and efficacy standards.

- a. *Standardize and clarify regulatory process.* The FDA, in collaboration with its upstream development government partners, must address development and standardization of regulatory processes that will provide needed transparency to MCM developers. The MCM industry needs to understand all elements of the process, and the government needs to mitigate the inherent risk. Several areas of regulatory reform should be considered- for example, reducing risk associated with clinical trials, and allowing companies to focus their resources on development. Through P.L. 115-92, Congress authorized DOD to request, and FDA to provide, assistance to expedite the FDA review process for MCM for military personnel. DOD and FDA have now put a work plan in place to coordinate planning for this process. FDA and BARDA should develop a parallel plan. Expedited release testing and a plan for increased usage of emergency use authorizations (EUAs) should be addressed as part of this plan.
- b. *Expedite release testing:* Even with a vaccine platform, the response time to produce a vaccine for the foreseeable future will be 6-12 months for mass-produced product. While maintaining safety and efficacy standards, acceptable FDA release testing during an outbreak might be different from acceptable release testing at other times. FDA should consider options. For instance, FDA might release products for use on an interim basis with final release testing to follow. FDA might identify suitable surrogates in place of full toxicology panels- or at least utilize a process to pre-identify what those surrogates would be. FDA should describe what an accelerated schedule would look like in an emergency. This will be especially important for platforms that could address multiple infectious diseases. Once in place, manufacturers could then propose specific schedules for a given MCM.
- c. *Examine increased usage of Emergency Use Authorizations:* EUAs are designed for those MCM that are sufficiently well characterized to be of likely clinical benefit in an emergency. FDA essentially certifies that a given MCM fulfills EUA requirements. FDA should determine when more aggressive utilization of EUAs would be appropriate.

5. Improve contracting authorities. BARDA must be empowered to make decisions in the best interest of fulfilling its mission. This means ensuring that the contracting process is as smooth, flexible, and transparent as possible. Other Transactional Authority (OTA) is most prominent among the existing contracting authorities that would incentivize MCM partnerships, yet it is utilized very rarely and limited by the statute that provided OTA authority to BARDA.

- a. *Amend the OTA statute.* Congress modeled the OTA authority addressed in the *Pandemic All-Hazards Preparedness Act (PAHPA)* after DOD's OTA statute. In its reauthorization of *PAHPA*, Congress should customize OTA authority to fit BARDA's needs. Congress should also remove references to DOD and the need for approval by the senior executive for projects above \$20 million (as it did previously for DOD). OTA contracts should become far more common than they are now, perhaps as common if not more than FAR-based contracts.
- b. *Adopt OTA for the CIADMs:* FAR-based contracting does not work for rapid response procurements. Using OTA for the ADMs is critical to prevent abandonment of partnerships when rapidity is imperative, when the science does not go as planned, and when

intellectual property and FAR-based requirements arise. DOD has adopted this OTA-based model for its ADM.

- c. *Move contracting authority back to BARDA.* In accordance with Blue Ribbon Study Panel Recommendation 29a (*A National Blueprint for Biodefense*, 2015), and the *21st Century Cures Act* Section 3082, contracting authority should be the exclusive responsibility of BARDA, not the office of Acquisition, Management, Contracts and Grants in the Office of the ASPR. This move must be finalized.

6. Foster innovation and new capabilities. The government often bases MCM-related plans on budgets instead of basing budgets on need. A similar mindset is seen with the government's approach to industry, often issuing solicitations to assess existing capabilities, rather than fostering new capabilities to meet national security needs. At the time of its authorization in *PAHPA*, Congress envisioned BARDA to be on the leading edge of MCM innovation. Over the past decade, BARDA has focused on more, well-established, product development technologies and investments in technologies closer to full maturity. This approach certainly justified much of the development portfolio. Live viral vaccine platforms and therapeutics based on monoclonal antibodies may well provide near- to medium-term solutions. Yet BARDA needs to devote sufficient resources to novel and high-risk product development activities in parallel with their less risky investments.

- a. *Invest in novel and high-risk products.* Meeting emerging national security threats will require BARDA to employ a high-risk, high-reward model for at least a portion of its investments. Instead of issuing solicitations to assess current industry capabilities, agencies should aggressively work with the private sector to build capabilities to meet national security needs. While investment in tried-and-true technologies will remain important, aggressively pursuing technologies that fall outside BARDA's comfort zone is imperative. The *21st Century Cures Act* authorized the Director of BARDA to engage an independent, non-profit innovation partner. BARDA should leverage this opportunity to dedicate additional resources to high-risk, high-reward outputs. It should further consider the role of the animal sector in providing needed technological advancements. The animal sector has existing markets for certain pharmaceuticals (for instance, with respect to coronaviruses and influenza viruses, which happen to be the most significant viral pandemic threats to the human population) that are lacking in the human sector. A shared interagency approach to planning for, and funding in, such areas could lead to needed innovative breakthroughs. Precedence for interagency funding mechanisms can be found in the funding HHS provided to USDA in 2009 to conduct domestic biosurveillance for swine influenza virus, a pathogen with minimal health impacts on the animal carrier but large potential impacts on public health.

- b. *Invest in rapid diagnostics.* The nation needs to invest far more in patient-side, point-of-care diagnostics.

Diagnostics can guide prioritization of MCM resources, but MCM conversations often refer only to vaccines and therapeutics, omitting diagnostics altogether. Rapid diagnostics cannot continue to be an afterthought. In accordance with Blue Ribbon Study Panel Recommendation 30a (*A National Blueprint for Biodefense*, 2015), DOD and BARDA need to invest in rapid diagnostics as a core element of their MCM portfolios. This work should identify generalized biomarkers that would enable such technologies.

- c. *Drive decision-making with early warning and predictive tools.* Leadership has yet to embrace predictive science as a core capacity that can support traditional and transformative MCM development. Advances in genomics and proteomics, risk mapping, and biosurveillance data analytics should all be leveraged to create early warning that could both inform and spare the stockpile. Budget requests and corresponding appropriations should support these efforts and ensure that they are an integral part of the federal MCM development and procurement strategy by aligning MCM investments with the threats identified through early warning programs.

7. Establish end-to-end enterprise coordination. Although PHEMCE was envisioned as a coordinating body for the federal MCM enterprise, it has been too HI·IS-centric to do this effectively. Development of a far more forward-looking process -from idea to procurement to dispensing- is needed. As the Office of the ASPR reimagines the end-to-end nature of the enterprise, it has an opportunity to address some specific challenges in the current construct.

- a. *Improve interagency product transitions.* Successful research projects at the National Institutes of Health, DARPA, or other agencies, must begin competition anew for advanced development- if advanced development funding is even available or prioritized. This creates major bureaucratic hurdles to product advancement. The National Biodefense Strategy should direct the creation of more streamlined interagency transition mechanisms. A wards can be structured to assume transition from one agency to the next.
- b. *Transfer management of the Strategic National Stockpile under specific conditions.* In the President's Budget Request for FY 2019, the Administration moved management responsibility of the Strategic National Stockpile (SNS) from the Centers for Disease Control and Prevention (CDC) to the ASPR. CDC management of the SNS has been inadequate, resulting in industry confusion and losses when the agency suddenly decided to remove elements from the stockpile that it had previously approved. The Administration made this move, in part, to better enable HHS leadership to direct acquisition for, and deployment of, the SNS. The move has the potential to create a more cohesive development-to- distribution structure and apply more process certainty to procurement decisions. Concerns about how BARDA and the SNS will interact once the move is finalized, and whether investments made by BARDA will inadvertently or intentionally force the SNS to acquire those MCM it developed, must be addressed. Congress should authorize the transfer of management of the SNS to the ASPR only if it also requires the ASPR to fix SNS-related problems that the CDC and state, local, tribal, and territorial (SLTT) partners previously encountered or created, and to put controls in place to prevent automatic uptake of BARDA products by the SNS just to demonstrate BARDA success. Congress should also direct the ASPR to establish a meaningful SNS training program for SLTT partners that focuses on more than just anthrax, takes SLTT ability to distribute SNS pallets upon receipt into consideration, and does not assume distribution will occur the same as in the military.
- c. *Produce an MCM response framework.* In accordance with Blue Ribbon Study Panel Recommendation 22a (*A National Blueprint for Biodefense*, 2015), the Office of the ASPR, CDC, and the Federal Emergency Management Agency should, together with non-federal partners, identify requirements and capacities needed to achieve successful distribution and dispensing of MCM from the SNS as well as from local

caches. The framework they develop must address unresolved issues. A progressive and innovative approach should push beyond what a given agency might devise and the bureaucratic impediments associated with a federal-only distribution system. If implementation exceeds funding available through current grant allocations, additional funding must be requested.

Thank you for considering these findings and recommendations. Please contact Dr. Asha M. George, Panel Executive Director, at (202) 974-2416 or Asha.George@BiodefenseStudy.org with further questions.

Sincerely,

Joseph I. Lieberman, Chair
Donna E. Shalala
James C Greenwood
Thomas J. Ridge, Chair

ONE HUNDRED FIFTEENTH CONGRESS
Congress of the United States
House of Representatives
COMMITTEE ON ENERGY AND COMMERCE
2125 Rayburn House Office Building
WASHINGTON, DC 20515-6115

July 12, 2018

Dr. Rick A. Bright
Director, Biomedical Advanced Research and Development Authority
Deputy Assistant Secretary, Office of the Assistant Secretary for Preparedness and Response
U.S. Department of Health and Human Services
200 Independence Avenue, S.W.
Washington, DC 20201

Dear Dr. Bright:

Thank you for appearing before the Subcommittee on Oversight and Investigations on June 15, 2018, to testify at the hearing entitled "The State of U.S. Public Health Biopreparedness: Responding to Biological Attacks, Pandemics, and Emerging Disease Outbreaks."

Pursuant to the Rules of the Committee on Energy and Commerce, the hearing record remains open for ten business days to permit Members to submit additional questions for the record, which are attached. To facilitate the printing of the hearing record, please respond to these questions with a transmittal letter by the close of business on Thursday, July 26, 2018. Your responses should be mailed to Ali Fulling, Legislative Clerk, Committee on Energy and Commerce, 2125 Rayburn House Office Building, Washington, DC 20515 and e-mailed in Word format to Ali.Fulling@mail.house.gov.

Thank you again for your time and effort in preparing and delivering testimony before the Subcommittee.

Sincerely,
Gregg Harper
Chairman
Subcommittee on Oversight and Investigations

**HOUSE ENERGY AND COMMERCE COMMITTEE, SUBCOMMITTEE ON
OVERSIGHT AND INVESTIGATIONS, "THE STATE OF U.S. PUBLIC
HEALTH BIOPREPAREDNESS: RESPONDING TO BIOLOGICAL
ATTACKS, PANDEMICS, AND EMERGING INFECTIOUS DISEASE
OUTBREAKS," DR. RICK BRIGHT, DIRECTOR OF ASPR'S
BIOMEDICAL ADVANCED RESEARCH AND DEVELOPMENT
AUTHORITY, FRIDAY, JUNE 15, 2018**

The Honorable Gregg Harper

1) In the 2017 update to HHS' Pandemic Influenza Plan, HHS provided benchmarks for manufacturing and distributing vaccines during declared influenza pandemics. HHS stated that it aims to ensure that limited vaccine distribution occurs within 12 weeks of a pandemic being declared, with distribution sufficient to meet overall public demand occurring within 16 weeks. Could you tell us why this process seemingly takes so long, and provide any recommendations for improving it? If the 12 and 16-week benchmarks are HHS's goals, what are our current capabilities?

ASPR Response:

Domestic manufacturing capacity for pandemic influenza vaccine is a critical component of pandemic preparedness to ensure vaccine is available as soon as possible after emergence of a pandemic virus. ASPR/BARDA has made significant gains in pandemic influenza vaccine preparedness over the last 10 years, including supporting the licensure of faster, more flexible cell-based, recombinant and adjuvanted influenza vaccines and modernizing and expanding domestic manufacturing capabilities. These advancements have dramatically increased the domestic influenza vaccine antigen capacity increasing from 60 million doses to 600 million doses.

Building on these successes, and to ensure vaccine is available within 12 weeks of pandemic declaration, ASPRJBARDA has a multifaceted approach in place. First ASPR/BARDA is partnering with companies to support the development of novel technologies that rely less on viral growth properties to improve the speed and robustness of vaccine production. For example, ASPRJBARDA supported the first licensed recombinant influenza vaccine (Flublok®), and ASPRJBARDA continues to fund recombinant vaccine-related efforts, moving away from the slow, inflexible production of vaccine in eggs. Second, ASPRJBARDA is supporting the sustainment of domestic production capabilities to ensure vaccines are available when necessary. Third, ASPRJBARDA is supporting further development of recombinant and cell-based vaccines through comparative efficacy clinical studies to expand use indications for a broad range of high- risk and special populations. Fourth, ASPRJBARDA is supporting the addition of currently approved adjuvanted influenza vaccines for all ages into both seasonal and pandemic vaccines, while also developing additional adjuvant options that provide safe and enhanced effectiveness to influenza vaccines that are faster to produce. Lastly, ASPRJBARDA is targeting advancements in vaccine delivery and administration to develop new approaches that would reduce reliance on needles and syringes supply chain surge capacity and allow faster and more efficient immunization with pandemic vaccine.

2) In general, what is the shelf-life for the H7N9 influenza strain vaccine that is in BARDA's pre-pandemic stockpile that will protect against the 2013 H7N9 strain? When was the last time BARDA performed a potency test on these vaccines?

ASPR Response:

The pre-pandemic vaccine made in eggs against the 2013 H7N9 avian influenza virus strain is very stable, with over 80% stability as of the last potency test conducted November, 2017. The most recent potency testing for the egg based vaccine was performed in May 2018 and we are awaiting results of this testing.

3) How serious of a pandemic threat does the BARDA view the 5th wave H7N9 influenza strain, currently circulating in China? If a pandemic were to occur, how severely would it impact public health? Is BARDA currently overseeing the manufacturing of a vaccine for storage in its pre-pandemic stockpile which will match this H7N9 influenza strain?

ASPR Response:

BARDA views the 5th wave H7N9 influenza outbreak as a serious concern, as reflected by the high Influenza Risk Assessment Tool (IRAT) score assigned by CDC. Since this assessment system, which assesses the threat of influenza viruses with pandemic potential, was initiated in 2012, the 5th wave H7N9 strain has the highest Potential Impact Risk of any influenza strain evaluated.

Given the human mortality rate seen to date, if the viruses changed to allow them to spread easily between humans, the impact on public health could be catastrophic in the absence of effective medical countermeasures such as vaccines. There is also evidence that some H7N9 influenza viruses may be resistant to most available antiviral drugs.

In response, BARDA produced bulk vaccine, currently held in storage, which matches the 5th wave H7N9 strain. Additionally, the National Institutes of Health (NIH) and BARDA are conducting clinical trials to better understand optimal vaccination approaches in the event mass vaccinations are necessary.

4) How much is BARDA currently spending on CARB-X? Does the agency anticipate maintaining this level of spending over the next five years?

ASPR Response:

BARDA established CARB-X in collaboration with the NIH's National Institute of Allergy and Infectious Diseases in 2016. CARB-X, an innovative public-private partnership that addresses the threat of antibiotic resistant bacteria, has received \$85 million in support from BARDA over two years. CARB-X is also funded by the Wellcome Trust. In 2018 the Bill & Melinda Gates Foundation and the United Kingdom Government's Department of Health and Social Care joined as funding partners. BARDA's support for new antibiotics and diagnostics is critical to address 21st century health security threats including genetically engineered bacterial pathogens, complications of bacterial infections as a result of exposure to priority threats such as nuclear and chemical agents, and to quickly identify bacterial pathogens and their susceptibility to antibiotics. BARDA anticipates continued support based on availability of funds.

5) What is the PHEMCE's role in making a material threat determination, and how can the length of time it takes for such a determination be reduced?

ASPR Response:

The Public Health and Emergency Medical Countermeasure Enterprise (PHEMCE), a Federal advisory and coordinating body led by ASPR, does have a role in advising on medical countermeasure requirements for national security material threats identified by the Department of Homeland Security (DHS). DHS's newly established Countering Weapons of Mass Destruction Office issues material threat assessments (MTAs) and the Secretary of the Department of Homeland Security (DHS) issues material threat determinations (MTDs). MTAs and MTDs are done in collaboration with other interagency departments, but the responsibility for generating these national, strategic overviews and quantification of the threat is identified by statute (section 319F-2(c)(2) of the Public Health Service Act (42 U.S.C. 247d-6b(c)(2)), added by the Project BioShield Act of 2004") as a DHS authority and responsibility. The PHEMCE benefits from these determinations and uses them to forecast

medical countermeasure requirements (type, quantity, special considerations). ASPR is currently working with other PHEMCE interagency partners to evaluate and identify opportunities to streamline and speed up these deliberative steps. We would be pleased to brief the Committee on potential process improvements after the evaluation is completed.

6) After ASPR assumes operational control of the Strategic National Stockpile on October 1, 2018, what role will CDC play in support of the stockpile's mission?

ASPR Response:

ASPR recognizes and appreciates the tremendous expertise of CDC subject matter experts including on infectious diseases, other public health threats, epidemiological and laboratory surveillance, as well as understanding of the capabilities of state and local public health departments. CDC is an active partner on the PHEMCE, which is led by ASPR and provides a venue for sharing information across HHS agencies and with interagency partners with a role in medical countermeasures requirement setting, research, development, regulatory review, procurement, stockpiling, distribution and use. CDC will remain an active participant in all PHEMCE workgroups and committees.

In order to ensure a smooth transition of the Strategic National Stockpile with no degradation of operational capability, ASPR and CDC have set up several joint transition workgroups to evaluate all aspects of the program transition. Some of the details involved in the transition have not been finalized. However, we would be pleased to provide a full briefing for Committee staff at any time before the end of the fiscal year. Subsequent to this hearing, the SNS successfully transferred from CDC to ASPR on October 1, 2018.

CDC will maintain its strong working relationships with state and local public health agencies, playing a key role in distribution and dispensing of medical countermeasures. CDC will accomplish this by continuing to provide technical guidance and funding through cooperative agreements and embedding experts in state and local health departments. Coordination with state and local agencies will be enhanced by incorporating ASPR's extensive relationships with health care organizations and emergency management agencies.

Further, to continue to increase collaboration across the Department, ASPR has invited and instituted a new senior CDC liaison who is working within the ASPR Immediate Office.

7) How prepared are the nation's hospitals to respond to biological threats or infectious diseases? What are the most pressing challenges facing non- governmental health systems and what could we do to improve their response capabilities?

ASPR Response:

Since the Hospital Preparedness Program (HPP) was established, investments have been made to enhance the overall preparedness of the nation's healthcare infrastructure. Initially, HPP supported the procurement of materials and supplies (e.g., generators, masks, etc.) that would be used should a community be impacted by a public health or medical event. In 2012, HPP shifted its focus from purchasing supplies to investing in health care coalitions (HCCs). HCCs are groups of health care and response organizations that collaborate to prepare for and respond to medical surge events. HCCs incentivize diverse and often competitive health care organizations to work together. During recent events, ranging from mass shootings (e.g., Las Vegas, Florida night club), hurricanes (e.g., Matthew, Harvey, Irma, and Maria), and the most

recent tornados in Iowa, we have witnessed the value of the HCCs in enabling communities to quickly assess healthcare capabilities to continue to support communities without requesting assistance from the federal government.

Prior to the 2014 Ebola outbreak in West Africa, the United States did not have an organized, systematic approach to preparing for, and responding to, an outbreak of a highly infectious pathogen. CDC in collaboration with ASPR developed a tiered approach to prepare U.S. health care facilities to safely and rapidly identify, isolate, evaluate, and manage, travelers or patients who have possible or confirmed Ebola. This included providing rapid technical assistance to hospitals strategically located near airports with a large number of travelers returning from Ebola-affected countries and in communities where large numbers of persons from these West African countries reside. To support this, HPP provided awardees with approximately \$214 million of Ebola emergency supplemental funding to establish a nationwide, regional treatment network for Ebola and other infectious diseases. The funding provided through HPP Ebola Preparedness and Response activities is intended to establish the foundation required for the nation's health care system to safely and successfully identify, isolate, assess, transport, and treat patients with Ebola virus disease or under investigation for Ebola (or other highly infectious diseases). Through this mechanism, ASPR awarded cooperative agreements to all 50 states, Washington D.C., all U.S. territories and freely associated states, and select metropolitan jurisdictions, over a five-year project period. Additionally, ASPR competitively awarded funding to 10 regional Ebola and other special pathogen treatment centers (i.e., one in each of the 10 HHS regions).

Additionally, to prepare for, and provide safe and successful care of patients with Ebola, HHS (in a collaboration between ASPR and CDC) awarded funding to establish a National Ebola Training and Education Center (NETEC). The NETEC provides expertise, training, technical assistance, peer review, monitoring, and recognition to state health departments, regional Ebola and other special pathogen treatment centers, state- and jurisdiction-based Ebola treatment centers, and assessment hospitals. NETEC is a consortium of three U.S. health facilities that safely and successfully treated a confirmed Ebola patient- Emory University in Atlanta, Georgia; University of Nebraska Medical Center/Nebraska Medicine (UNMC) in Omaha, Nebraska; and the New York City Health and Hospitals Corporation/HHC Bellevue Hospital Center in New York, New York.

Going forward and leveraging the best practices from investments made with the Ebola supplemental appropriations, ASPR is developing innovative tiered regional demonstration projects that can serve as a model for building a regional disaster health response system across the country. Subsequent to this hearing, ASPR awarded two grants- Nebraska Medicine in Omaha, Nebraska and Massachusetts General Hospital in Boston, Massachusetts to conduct pilot projects that show the potential effectiveness and viability of a Regional Disaster Health Response System (RDHDS).

The Honorable Michael C. Burgess

1) Dr. Bright, in 2010, BARDA established three centers to develop and manufacture medical countermeasures, such as vaccines and therapeutics, to protect our citizens during public health emergencies. Texas A&M's Center for Innovation in Advanced Development

and Manufacturing is one of these centers, and was intended to focus on surge capacity for flu vaccines. I understand that the initial contract period with the Texas facility expires at the end of this month. How does BARDA plan to utilize these centers in the future? Will BARDA maintain and grow existing partnerships that have the infrastructure to deploy capabilities in the wake of a crisis?

ASPR Response:

BARDA established the Centers for Innovation in Advanced Development and Manufacturing as public private partnerships in 2012. The program has made important investments in the domestic capacity for medical countermeasure production for public health emergencies. Each of the three centers in Texas, Maryland and North Carolina were funded to establish pandemic influenza vaccine manufacturing surge capacity, core service capabilities, and workforce development programs. Program successes include: process updates that resulted in a fourfold increase in yield for the domestically-produced cell based inactivated influenza vaccine; the development of commercially run facilities in Texas and Maryland; and a well- established workforce development program at Texas A&M in College Station, Texas. BARDA recently issued a six month extension to the base period for the Texas A&M center to facilitate additional partnering opportunities.

BARDA is currently evaluating how best to sustain and strengthen the domestic medical countermeasure manufacturing capabilities needed for the nation to be optimally prepared for 21st century health security threats.

2) How do you communicate with centers such as Texas A&M about what medical countermeasures they should develop? How involved is BARDA in helping these "centers" identify additional partners with whom they can work?

ASPR Response:

Each Center has a designated federal contracting officer representative and contracting officer. These officials monitor completion of contract requirements and subsequent task orders that the centers have to meet per the terms of the contract. BARDA also holds frequent site visits and regular status calls with each of the Centers and has encouraged potential partner discussions through those interactions. Lastly, the Centers are required to maintain other commercial business/partnerships to make use of established capacity, to offset costs, and be a shared resource.

The Honorable Frank Pallone, Jr.

1) With respect to the three types of threats we often hear about- natural, intentional, and accidental-to what extent do preparedness efforts for the different types of threats overlap?

ASPR Response:

ASPR coordinates with states and local officials before, during, and after emergencies to test existing response capabilities. While each incident, whether naturally occurring, man-made, or accidental, has its own considerations, there are common requirements that spread

across all emergencies. Common elements include supporting situational awareness and information sharing between and among all supporting officials, supporting and augmenting local healthcare entities in treating the impacted population, ensuring critical assets are available to communities in need, and supporting the recovery of the community.

Investing in technologies that have the potential to yield multiple diagnostics, vaccines or therapeutics against different pathogens ensures that capabilities are nimble and flexible to support vaccines and therapeutics for future threats. Examples of this type of investment are how BARDA is supporting development of vaccines against the Ebola Zaire virus. Currently, BARDA is supporting two candidates under Project BioShield. There is the potential that same vaccine platform used to develop the Ebola Zaire virus vaccines could be used to develop vaccines against Ebola Sudan or Marburg viruses, by replacing just one element (glycoproteins). In addition, the vaccine platform could be used to express proteins from newly identified pathogens and expedite development of a vaccine for clinical trials.

2) How can we plan long-term therapeutics and vaccines in order to respond to outbreaks that we cannot yet anticipate?

ASPR Response:

It often takes 10 or more years and over \$1 billion to develop a new drug or vaccine.

ASPR/BARDA utilizes many of the innovative authorities authorized by amendments made by the Pandemic and All-Hazards Preparedness Act to the Public Health Service Act to support development of medical countermeasures. Authorities like Other Transaction Authorities (OTA) mean ASPR/BARDA can enter into innovative agreements to support development and procurement. As an example, the first BARDA OTA was within the broad spectrum antimicrobial program. Currently three out of six BARDA OTAs are focused on development of antimicrobial products. BARDA has also utilized CARB-X- an innovative public-private partnership conducted under a cooperative agreement- to address the threat of antibiotic resistant bacteria. CARB-X involves seven partners in the U.S. and U.K. and is backed with half a billion dollars in funding. \$85 million in BARDA CARB-X investment resulted in nearly \$500 million in private equity follow on investment. The partnership has 28 different companies making novel antibacterial drugs, vaccines, and diagnostics, including eight new classes of antibiotics.

3) BARDA's CARB-X program is developing many nontraditional products at the preclinical stage. Can you briefly explain why you have supported these products, and what BARDA is doing to make sure that enough products move on to clinical trials?

ASPR Response:

Under the National Action Plan for Combating Antibiotic Resistant Bacteria (CARB), published by the White House in 2015, ASPR was directed to establish a biopharmaceutical accelerator in collaboration with NIH. BARDA established CARB-X in collaboration with the NIH's National Institute of Allergy and Infectious Diseases (NIAID), in NIH, in 2016. This was two years ahead of the three year milestone to establish the partnership. CARB-X is an international consortium of funders including BARDA, NIAID, Wellcome Trust, the Bill & Melinda Gates Foundation, and the UK Government's Department of Health and Social Care.

BARDA does not support the product portfolio alone; instead it is a collaborative effort across multiple, international organizations. BARDA funds non-traditional products because antibiotics are a solution but not the only solution for antibiotic resistant bacteria. In addition, all of the candidate products supported under CARB-X can support new treatment options for genetically engineered biothreat pathogens or the secondary bacterial infections that will result from exposures to threat agents, such as ionizing radiation from a nuclear blast or burn injuries resulting from nuclear or chemical agents.

Five products under the CARB-X portfolio have advanced to phase I clinical trials with more expected in the coming years. Candidate products may move into clinical trials when clinical trial proposals and data to support investigational new drug status are submitted to the FDA and data review does not show prohibitive adverse risk-benefit concerns. BARDA, as a funder and as a member CARB-X, works closely with the cooperative agreement awardee's program team to make sure that products are meeting the scientific milestones to advance in development.

4) Can you explain what BARDA is doing to foster public-private partnerships, and why this is important?

ASPR Response:

BARDA established and manages the Tech Watch Program (<https://www.phe.gov/about/barda/Pages/BARDA-techwatch-Mtgs.aspx>). Under Tech Watch, companies can come and discuss their technologies with BARDA to determine if the product is appropriate for BARDA to consider funding in the future. If the program does not align with BARDA priorities, we will refer them to other federal agencies that may be able to assist them with development. BARDA holds 150-200 Tech Watches per year.

BARDA also holds an annual BARDA Industry Day (BID), consistent with its authorities under the Public Health Service Act. This meeting brings together BARDA and other PHEMCE partners with industry, academic, and non-government organizations. It provides an opportunity for BARDA to highlight current and future strategic plans and priorities. BID also provides companies the opportunity to discuss their programs and how they might be able to address existing or future requirements.

Lastly, BARDA attends national and international conferences to discuss our portfolio of products, potential additional candidates, and our strategic plans. Numerous stakeholders attend these conferences allowing for another venue for BARDA to meet with potential partners.

BARDA cannot develop countermeasures alone. Public-private partnerships are critical to the continued success of BARDA and all of the ongoing medical countermeasure development initiatives.

5) ASPR has a number of programs in place, including the Hospital Preparedness Program and the Medical Reserve Corps, which are designed to help ensure readiness at the state and local level. How do these programs ensure that our front-line responders are able to respond effectively in a public health emergency situation?

ASPR Response:

ASPR's mission is to save lives and protect Americans from 21st century health security threats. On behalf of the Secretary of HHS, ASPR leads public health and medical preparedness for, response to, and recovery from disasters and public health emergencies.

All of ASPR's programs and capabilities work together to create "unity of command" by consolidating Federal nonmilitary public health and medical preparedness and response functions. ASPR coordinates across HHS and the Federal interagency to support state, local, territorial, and tribal health partners. ASPR works to enhance medical surge capacity by organizing, training, equipping, and deploying HHS public health and medical personnel, such as National Disaster Medical System (NOMS) teams, and providing logistical support for HHS personnel responding to public health emergencies. ASPR supports readiness at the state and local level by coordinating federal grants and cooperative agreements, such as the Hospital Preparedness Program (HPP), by programs like the Medical Reserve Corps (MRC), and carrying out drills and operational exercises. For example, HPP prepares the nation's health care system to save lives during emergencies and disasters. It is the only source of federal funding for health care system readiness. HPP prepares the health care system to save lives through the development of health care coalitions (HCCs). HCCs are groups of health care and response organizations that collaborate to prepare for and respond to medical surge events. HCCs incentivize diverse and often competitive health care organizations to work together, allowing them to plan together and respond jointly in emergencies.

Specific to how ASPR supports first responders, ASPR routinely partners with state and local governments, hospitals, and responders to conduct drills and exercises to test various aspects of medical response capabilities. Drills and exercises provide opportunities at all levels to examine plans, procedures, and capabilities and to work with all government partners to employ resources in response to a specific event or scenario. One recent example is ASPR's Tranquil Terminus Exercise that brought together four regions, seven states, eight cities and three federal departments to test the nation's ability to transport patients with a highly infectious disease. Communities and responders benefitted by having the opportunity to test and rehearse plans with all partners participating. They learned from each other as well as identified best practices for inclusion in their plans and procedures.

6. CDC recently concluded an operational readiness review to assess whether state and local governments and public health services will be able to effectively get medical countermeasures to the appropriate person at the appropriate time. How does BARDA work with CDC and health departments to ensure that we develop countermeasures with this "last mile" of delivery in mind?

ASPR Response:

Through its active role in PHEMCE, CDC shares information across HHS agencies, including ASPR/BARDA, who have a role in medical countermeasures requirement setting, research, development, regulatory review, procurement, stockpiling, distribution and use. Through this channel, as well as through established direct program-to-program collaborations with BARDA, CDC provides input on how countermeasure development can better meet end user needs. This includes criteria for how products developed may be stored and packaged to improve/simplify stockpiling and distribution, improved product delivery

systems, simplified dosing considerations, etc. These factors assessed by CDC, impact how products are distributed, dispensed/administrated and used.

ATTACHMENT-ADDITIONAL QUESTIONS FOR THE RECORD

The Honorable Gregg Harper

1. Have there been any laboratory-acquired infections or potential exposures to pathogens at CDC labs during this past year? If so, what was the nature of the exposure or infection, and were any hospitalizations required as a result?

2. How serious of a pandemic threat does the CDC view the 5th wave H7N9 influenza strain, currently circulating in China? If a pandemic were to occur, how severely would it impact public health?

3. What are the present challenges that are preventing the broader utilization of cell-based influenza vaccines, and what steps can be taken to become less reliant on egg-based vaccines? What are the advantages of utilizing cell-based influenza vaccines over egg-based ones?

4. Is there currently an approved anthrax vaccine that can be administered to children? If so, what are the dosing guidelines for pediatric administration? If not, are there any pediatric anthrax vaccines currently under development, and what is the status of this development?

5. Were any FY 2017 funds for the non-procurement costs of the Strategic National Stockpile (SNS) used for any CDC expenses outside of the SNS program? If so, please identify the type and amount of these expenses.

6. How many laboratories currently make up the Laboratory Response Network (LRN)?

7. How much funding is there for the LRN in FY 2018?

The Honorable Michael C. Burgess

1. Dr. Schuchat, in your written testimony you mentioned CDC's use of electronic data systems to monitor population health information. How does CDC use and disseminate this data such that it can coordinate a timely response? Is the data platform that CDC uses integrated or interoperable with other biosurveillance platforms?

The Honorable Frank Pallone, Jr.

1) How does CDC ensure that its laboratories are gathering data from as many sources as possible?

a. Do you need additional resources to help you analyze this data more effectively?

d) Please provide an update on CDC's concerns about the growth of antibiotic resistant bacteria?

e) In the case of an emergent biological threat, how does CDC's Emergency Operations Center coordinate the response at the front lines, such as at the state and local level?

- f) Please describe how CDC uses its Public Health Emergency Preparedness Cooperative Agreement Program to help states and local municipalities identify and address gaps in preparedness. Is there anything you need from Congress to make sure this program works as intended?
- g) What are the biggest challenges to successfully deploying countermeasures at the state and local level? How is CDC addressing these challenges?

**HOUSE ENERGY AND COMMERCE COMMITTEE, SUBCOMMITTEE ON
OVERSIGHT AND INVESTIGATIONS, “THE STATE OF U.S. PUBLIC
HEALTH BIOPREPAREDNESS: RESPONDING TO BIOLOGICAL
ATTACKS, PANDEMICS, AND EMERGING INFECTIOUS DISEASE
OUTBREAKS,” FRIDAY, JUNE 15, 2018**

The Honorable Gregg Harper

1) What do we need to do as a country to be better prepared for an outbreak of pandemic influenza in the U.S.?

NIAID Response:

The National Institute of Allergy and Infectious Diseases (NIAID), the lead institute for research on influenza at the National Institutes of Health (NIH), is conducting and supporting basic, translational, and clinical research that will improve our ability to prepare for and respond to potential pandemic influenza outbreaks. A particular challenge in preparing for an outbreak of seasonal or pandemic influenza is that current influenza vaccines do not provide protection that is long-lasting or effective against a large number of influenza virus strains. To address this challenge, NIAID is prioritizing the development of universal influenza vaccine candidates that could provide long-lasting protection against multiple influenza strains including those with pandemic potential.

NIAID is galvanizing research efforts to develop universal influenza vaccine candidates and convened influenza experts from the U.S. and throughout the world at a research agenda-setting workshop in 2017. Following this meeting, NIAID outlined its universal influenza vaccine research priorities in a strategic plan that focuses on three key areas: improving knowledge of the transmission and pathogenesis of influenza infection; characterizing influenza immunity and immune factors that correlate with protection against influenza; and supporting the design of universal influenza vaccines. NIAID is actively engaging federal partners, including U.S. Department of Health and Human Services agencies and other key domestic and international stakeholders involved in influenza vaccine research, to coordinate and advance activities outlined in the strategic plan. For example, NIAID continues to collaborate with the Biomedical Advanced Research and Development Authority (BARDA) to advance the development and clinical testing of promising influenza vaccine candidates. The additional \$40 million in funding for universal influenza vaccine research provided through the Consolidated Appropriations Act, 2018 (P.L. 115-141) will support targeted research investments for the development of universal influenza vaccines that could protect vaccinated individuals against seasonal or pandemic influenza virus strains.

In addition to pursuing universal influenza vaccine strategies, NIAID is working to develop novel vaccine production strategies - such as recombinant DNA manufacturing

techniques -that may allow for a more rapid production of targeted vaccines in response to newly emerging or changing strains of influenza virus than current egg and cell-based technologies. These vaccine production techniques could help to speed the availability of vaccines that protect against new or evolving pandemic influenza virus strains.

While investing in research to improve influenza vaccines, NIAID also continues to support the development of novel diagnostics to rapidly identify influenza viruses, including potential pandemic strains, and antiviral drugs that could help to limit influenza morbidity and mortality in a pandemic. NIAID will continue to play a key leadership role in seasonal and pandemic influenza outbreak preparedness and response efforts by conducting and supporting the basic, translational, and clinical research needed to identify and develop effective medical countermeasures.

2) In your testimony, you mentioned that there will be several iterations of a 'universal' flu vaccine. How many universal vaccine candidates are currently being developed at, or supported by, NIAID and what strains will they target? Where does this research currently stand? How many iterations of a universal flu vaccine does NIAID ultimately envision?

NIAID Response:

A truly universal influenza vaccine would represent a groundbreaking advance in the fight against influenza by providing protection against a number of seasonal and pandemic influenza virus strains. NIAID currently is exploring at least 10 different strategies toward the development of universal influenza vaccine candidates. Each of these strategies may have multiple vaccine candidates in various stages of development that are being investigated by NIAID intramural researchers or NIAID-supported grantees in academia and industry. Notable highlights of NIAID universal influenza vaccine research include the development of a ferritin nanoparticle-based vaccine candidate by the NIAID Vaccine Research Center (VRC), Phase I clinical trials of a VRC-developed DNA vaccine candidate using a prime-boost strategy with a standard inactivated seasonal influenza vaccine, and the recent launch of a NIAID-sponsored Phase II clinical trial to evaluate the M-001 vaccine candidate, which contains several influenza fragments recognized by the immune system that are common among multiple influenza virus strains. Additionally, NIAID is sponsoring a Phase I clinical trial to evaluate the safety and immunogenicity of a prime-boost regimen using an intranasal vaccine candidate followed by a licensed, quadrivalent seasonal influenza vaccine.

We anticipate that progress toward the goal of a universal influenza vaccine will occur in several stages, with each intermediary stage represented by several vaccine candidates that protect against progressively greater numbers of influenza virus strains. NIAID is pursuing strategies that could protect against all strains of a single subgroup of influenza virus, such as the H3N2 strains. This could be considered a universal influenza vaccine Version 1.0. As we make progress towards more broadly protective influenza vaccines, a Version 2.0 could protect against two or more subgroups of influenza, such as all H1N1 strains and all H3N2 strains. This may lead to developing a universal influenza vaccine candidate that by itself could durably protect against all subgroups of influenza, thereby protecting against virtually any influenza strain. Each universal influenza vaccine candidate will need to be evaluated over several influenza seasons to determine the level of protection that is induced, and the durability of that protection.

Version 1.0 of a universal influenza vaccine may be available in a few years, representing an incremental improvement on currently available influenza vaccines. A universal influenza vaccine that covers all major influenza strains may be many years away, with several iterations may be likely needed to ultimately achieve a broadly protective vaccine against all or nearly all influenza strains.

3) What are the present challenges that are preventing the broader utilization of cell-based influenza vaccines, and what steps can be taken to become less reliant on egg-based vaccines?

NIAID Response:

NIAID supports the development of flexible vaccine manufacturing processes, including the use of molecular biological techniques, to help shorten manufacturing times and increase production efficiency for current and future influenza vaccines. Barriers to the broader utilization of cell-based and recombinant technologies to produce influenza vaccines include differences in manufacturing needs, development costs, and public awareness of alternatives to egg-based influenza vaccines.

NIAID is working to address these challenges through the support of basic and translational research for the development and manufacture of novel influenza vaccine strategies. NIAID scientists have devised a new method to manufacture an experimental whole virus inactivated influenza vaccine using a cell-based system. This method would provide another alternative to currently licensed egg-based and cell-based influenza vaccines. NIAID researchers also are developing and evaluating an additional cell-based system for whole virus influenza vaccine candidates to try to determine the most efficient cell-based system to produce influenza vaccines, both in terms of manufacturing time and cost. Data from these NIAID-supported studies will help improve vaccine manufacturing processes and vaccine efficacy, leading to the design of better influenza vaccines. NIAID also has supported studies of improved vaccine strain selection and optimized high-yield vaccine strains as part of the Seasonal Influenza Vaccine Improvement (SIVI) initiative, an interagency collaboration launched in 2016.

In addition to supporting the development of innovative seasonal influenza vaccines, NIAID has made a strategic shift toward a research paradigm that features broader, more flexible vaccine platform technologies such as recombinant DNA manufacturing techniques that can be rapidly mobilized when pandemic influenza viruses emerge. NIAID continues to support the early development of candidate pandemic influenza vaccine candidates that can be transitioned to BARDA for advanced development, with the goal of Food and Drug Administration (FDA) licensure and potential inclusion in the Strategic National Stockpile. NIAID also will continue to work closely with industry partners to advance promising influenza vaccine candidates, including cell-based and recombinant vaccine strategies.

The Honorable Michael C. Burgess

1) Dr. Fauci, the National Institute of Allergy and Infectious Diseases is on the front lines of vaccine development, especially in the wake of Ebola and Zika hitting the United States.

You wrote an article in the Journal of the American Medical Association in November 2017 that detailed the critical role of biomedical research in pandemic preparedness. Can you share with us some of the research approaches NIAID uses to prepare for pandemics, such as a new flu strain, that have yet to hit our shores?

NIAID Response:

As outlined in the 2017 article in the Journal of the American Medical Association, *The Critical Role of Biomedical Research in Pandemic Preparedness*, comprehensive pandemic preparedness requires a multifaceted approach. A critical component is biomedical research to support the development of vaccines, diagnostics, and therapeutics that may be quickly deployed in response to an emerging or re-emerging infectious disease of pandemic potential. NIAID supports a comprehensive portfolio of basic research on microbiology and immunology to better understand the mechanisms of pathogenesis and immune responses, as well as applied and clinical research to evaluate candidate diagnostics, therapeutics, and vaccines. This strategic effort includes the pursuit of several research approaches, including: (1) research targeting specific pathogens; (2) prototype pathogen efforts, in which fundamental research to understand the disease caused by one pathogen may inform the development of countermeasures for a closely related pathogen; and (3) development of platform-based technologies and broad-spectrum products that may be easily and quickly deployed against multiple pathogens. NIAID research complements other elements of pandemic preparedness by improving understanding of infectious disease pathogenesis and by developing candidate medical countermeasures that could be used in a pandemic.

NIAID supports a broad portfolio of pathogen-specific basic, translational, and clinical research. NIAID investments in pathogen-specific research include priority pathogens of the United States Government as designated by the Centers for Disease Control and Prevention (CDC), as well as other emerging and re-emerging diseases identified as priority pathogens by NIAID. For example, NIAID supported development of m102.4, a candidate monoclonal antibody treatment for Nipah virus infection. NIAID also is supporting the development of improved influenza vaccine candidates, including universal influenza vaccines that could provide broad protection for a range of pandemic and seasonal influenza strains. Additionally, it was an NIAID investment in basic research nearly 40 years ago that enabled the development of the novel influenza antiviral Xofluza (baloxavir marboxil), which was approved for use in Japan in early 2018 and is currently undergoing FDA priority review for use in the United States.

NIAID has built upon increased understanding of infectious disease pathogenesis to move strategically toward a medical countermeasures research paradigm that features broader, more flexible platform technologies that can be used to respond to several biological threats. High-throughput sequencing and platform-based technologies are facilitating the development and manufacture of vaccines, targeted antibody therapeutics, and broad-spectrum antibiotics and antivirals by significantly decreasing the time from identification of a public health threat of an emerging infection to clinical evaluation of candidate countermeasures. For example, in 2015-2016 when Zika virus emerged in the Americas, clusters of microcephaly and other birth defects were identified, and a Public Health Emergency of International Concern was declared by the World Health Organization. NIAID scientists rapidly used Zika virus genetic sequence information to develop a DNA-based vaccine candidate that moved from concept to a first-in-human trial in less than four months.

The experimental DNA-based Zika vaccine, which currently is in Phase II/IIB clinical testing, was developed with a readily deployable DNA vaccine platform that is a form of gene-based immunization previously used by NIAID to develop a candidate vaccine for West Nile virus. The development of a broadly applicable platform technology facilitated an accelerated response to a previously unrecognized public health threat. As mentioned in the 2017 article in the *Journal of the American Medical Association*, NIAID is supporting development of additional vaccine platform technologies, including nanoparticle, virus-like particles, and mRNA platforms. NIAID also supports development of broad-spectrum therapeutics, including antiviral and antibacterial agents that have demonstrated activity against multiple viral or bacterial pathogens.

Together with academia, industry, and Public Health Emergency Medical Countermeasures Enterprise (PHEMCE) partners, NIAID remains committed to meeting public health emergency needs by advancing high-priority research to support development of medical countermeasures for emerging and re-emerging infectious diseases, including influenza viruses with pandemic potential. NIAID-supported research into specific pathogens, prototype pathogens, and the development of platform-based technologies will continue to play an essential role in PHEMCE pandemic preparedness and response efforts.

The Honorable Frank Pallone, Jr.

1) How can we plan long-term for therapeutics and vaccines in order to respond to outbreaks that we cannot yet anticipate?

NIAID Response:

NIAID supports a comprehensive portfolio of basic research on microbiology and immunology to better understand the mechanisms of pathogenesis and immune response, as well as applied and clinical research to evaluate candidate diagnostics, therapeutics, and vaccines. This strategic effort includes the pursuit of foundational platform approaches that could be used to develop medical countermeasures against multiple pathogens.

NIAID is pursuing the development of platform approaches including molecular biological technologies that could be rapidly mobilized to generate candidate vaccines against emerging infectious disease threats. For example, during the 2015-2016 Zika virus outbreak in the Americas, NIAID scientists developed a novel DNA-based vaccine for Zika virus using viral genetic sequence information. The candidate vaccine moved from concept to a first-in-human trial in less than four months, and currently is in a Phase II/IIB trial. In order to respond so quickly, NIAID utilized a readily deployable DNA vaccine platform that was previously used by NIAID to develop a candidate vaccine for West Nile virus. These types of genetic platforms could be used to respond similarly to multiple emerging and re-emerging infectious disease threats.

NIAID investments in basic, translational, and clinical research also are contributing to the development of novel broad-spectrum therapeutics that can target several pathogens. For example, NIAID has supported early-stage development of broad-spectrum antiviral agents such as BCX4430 (galidesivir), which has demonstrated activity against Ebola and other RNA viruses, and broad-spectrum antibacterial products, including a compound with activity

against the two different bacteria that cause tularemia and plague. Such broad-spectrum therapeutics may decrease the time necessary to identify and distribute an effective treatment during an outbreak setting.

NIH, led by the Fogarty International Center and NIAID, also supports the development of research infrastructure and partnerships in foreign countries to aid in the identification, monitoring, and response to the emergence and reemergence of infectious diseases. Long-standing international investments in disease monitoring and response made by NIH were vital in the immediate response to the 2014-2016 Ebola outbreak in West Africa and provided critical in-country expertise that helped to contain the spread of the disease. In addition, the clinical research partnership between NIAID and the government of Liberia, the Partnership for Research on Ebola Virus in Liberia (PREVAIL), demonstrated the ability to do rigorous scientific research in developing countries. The PREVAIL partnership enabled in-country clinical trials testing of several Ebola virus therapeutic and vaccine candidates, among them the ZMapp™ therapeutic, the Merck VSV vaccine, and the cAd3-EBOZ vaccine developed by the NIAID VRC in partnership with industry. NIAID, through a partnership with the French National Institute of Health and Medical Research (Inserm), the London School of Hygiene and Tropical Medicine, and the host country governments, has launched the Partnership for Research on Ebola VACcination (PREYAC), a Phase II clinical trial comparing three experimental Ebola vaccination strategies in Mali, Guinea, Sierra Leone, and Liberia. Medical countermeasures tested by the PREVAIL partnerships were recently deployed in the Democratic Republic of the Congo to help address an Ebola outbreak from May to July 2018, emphasizing the key contributions of this effort. NIAID-supported international research partnerships also contribute to the development of site infrastructure and sustainable research capacity in developing countries, enhancing global preparedness to respond to unanticipated outbreaks and to conduct clinical research to better understand the disease and to test candidate countermeasures during these outbreaks.

2) In your view, are there specific pathogens or diseases we should be most concerned with?

a. With so many dangerous pathogens, how do we prioritize research to try to target those posing the greatest threat?

NIAID Response:

NIAID prioritizes research and early-stage development of medical countermeasures against bioterror threats and emerging and re-emerging infectious diseases of public health importance. The persistent threat of pandemic influenza and other respiratory viruses that may spread quickly and cause significant morbidity and mortality, such as severe acute respiratory syndrome coronavirus (SARS-CoV) or Middle East respiratory syndrome coronavirus (MERS-CoV) remain a particular area of concern. NIAID maximizes its efforts to develop effective medical countermeasures against these, and other potential emerging and re-emerging diseases, by prioritizing research into broad-spectrum antibiotics and antiviral drugs, as well as efficient platform technologies to more rapidly develop vaccines and diagnostics for a variety of threat pathogens.

NIAID's efforts to develop a broader, more flexible research paradigm is yielding scientific advances that will facilitate public health emergency preparedness and our ability to respond to emerging public health threats. NIAID is supporting the development of

diagnostics platforms capable of distinguishing between several pathogens, as well as broad-spectrum therapeutics, including novel antiviral agents, effective against several pathogens. In addition, NIAID is prioritizing the development of several vaccine platforms that could be used to quickly develop vaccine candidates against newly identified threats. This includes the DNA-based platform used to develop a candidate vaccine against Zika virus that moved from concept to a first-in-human trial in less than four months. The development of these and other broad-spectrum therapeutics and platform technologies remains a NIAID priority.

In addition to supporting the development of platform technologies and broad-spectrum therapeutics that may decrease response time in the event of a pandemic, NIAID also supports a targeted portfolio of basic, translational, and clinical research on priority pathogens with pandemic potential, including influenza and other respiratory viruses. This includes detailed studies of immune system responses to infection, as well as research to better understand the transmission, evolution, and pathogenesis of the viruses to inform the development of vaccines, diagnostics, and therapeutics that could be deployed during a pandemic. The NIAID Vaccine and Treatment Evaluation Units currently are conducting two Phase II clinical trials of a new vaccine candidate to protect against emerging H7N9 influenza virus strains, and NIAID intramural scientists are conducting clinical studies of prime-boost vaccine regimens for swine (H1) and avian (H7) influenza viruses.

NIAID is galvanizing research efforts to support the development of universal influenza vaccine candidates. A universal influenza vaccine that is effective against both seasonal and pandemic influenza strains would be a vital tool to prepare for future pandemics, as well as to improve our ability to prevent seasonal influenza. In addition, NIAID is supporting novel antiviral therapies for influenza, including RNA polymerase inhibitors, peptide inhibitors, and next-generation neuraminidase inhibitors. NIAID support for influenza diagnostics research has led to the development of a rapid molecular *in vitro* assay recently cleared by the FDA to accurately distinguish influenza A from influenza B in nasal swab specimens.

NIAID continues to make progress against other respiratory viruses with pandemic potential. NIAID is supporting early-stage clinical trials of antibodies designed to treat people infected with MERS-CoV, as well as development of a vaccine candidate for MERS-CoV based on information from previous vaccine studies on SARS-CoV. NIAID-funded researchers also have identified a novel SARS-related virus, swine acute diarrhea syndrome coronavirus (SADS-CoV). SADS-CoV was responsible for 25,000 piglet deaths in China in 2016-17; however, no infections in humans have been identified. The identification of pathogens with zoonotic potential such as SADS-CoV that may emerge as human diseases contributes to our preparedness, as it may facilitate early identification if the pathogen becomes capable of causing disease in humans. NIAID will continue to prioritize research on pathogens with pandemic potential such as influenza and other respiratory viruses and support the development of platform-based technologies and broad-spectrum products that may be easily and quickly deployed against multiple pathogens.

3) Can you briefly explain the barriers that make it harder for scientists to discover new antibiotics?

NIAID Response:

NIAID supports a comprehensive basic research portfolio on antibiotic resistance to aid in the discovery of new antibiotics. NIAID antimicrobial resistance research includes the

elucidation of major mechanisms of pathogenesis, host-pathogen and drug-pathogen interactions, and the identification of new candidate antibiotics. NIAID has found that the major challenges in the development of new antibiotics are in the later stages of clinical development of these drugs. NIAID has identified three main barriers to the advanced development of new antibacterial therapeutics: 1) the scarcity of new antibacterial drug candidates effective against Gram-negative infections; 2) the challenge of enrolling patients in clinical trials needed to show efficacy of new therapeutics, especially in the case of Gram-negative drug-resistant infections; and 3) a lack of market incentives for pharmaceutical companies to invest in the final stages of antibiotic development and licensure. NIAID is working to address these challenges in several ways, including through the support of basic, translational, and clinical research to identify and advance promising antibacterial candidates to late-stage development. NIAID estimates that more than 25 percent of the antibacterial candidates currently in clinical development previously received some form of NIAID support.

NIAID is addressing these challenges by supporting early-stage development and clinical trials of new therapeutics to help offset the investment required to successfully test these therapeutics and bring them to market. The NIAID-supported Antibacterial Resistance Leadership Group (ARLG) has supported over 35 clinical studies investigating new therapeutics, optimized treatment regimens, diagnostic devices, and projects on antimicrobial stewardship. The ARLG places a priority on research involving Gram-negative bacteria that represent a major antimicrobial resistance threat. NIAID-supported scientists also completed two Phase I clinical trials for a new class of antibiotics (CRS3123) to treat *Clostridium difficile* infections, which are increasingly difficult to treat effectively. In addition, NIAID is supporting clinical trials to evaluate the efficacy of new therapeutic candidates, as well as new treatment regimens that utilize existing antibiotics in new combinations or regimens. NIAID also has solicited research for the development of tools to advance drug discovery of agents against Gram-negative pathogens through the "Partnerships for the Development of Tools to Advance Therapeutic Discovery for Select Antimicrobial-Resistant Gram-Negative Bacteria" program. NIAID is facilitating scientific discussions and partnerships to address key questions and challenges in the development of new antibiotics. NIAID and The Pew Charitable Trusts sponsored the 2017 scientific workshop entitled, "Challenges in the Discovery of Gram-negative Antibacterials: The Entry & Efflux Problem." The goal of the workshop was to identify next steps and opportunities for collaborations to determine factors that affect the entrance of antibiotics into, and accumulation within, Gram-negative bacteria to inform the identification and design of new types of antibiotics. Resolving these early-stage research questions will help address the growing threat of resistant Gram-negative bacteria by facilitating the later-stage development of promising new therapeutic candidates.

NIAID also addresses barriers to the advanced development of new antibacterial therapeutics by helping to de-risk antibacterial product development for researchers in industry and academia through targeted research support and services. NIAID supports the National Database of Resistant Pathogens, which contains genomic data for more than 205,000 drug-resistant microbes. This database was established by the NIH, in partnership with FDA and CDC, as a publicly available resource that scientists from all over the world can access to inform the development of novel antibacterial products. NIAID also funds the Centers of Excellence for Translational Research that have recently discovered a new class of antibiotics produced by soil-dwelling bacteria. These antibiotics, known as malacidins, have a

unique mechanism of action that may make the development of resistance less likely. NIAID also supports CARB-X, a unique public-private partnership led by BARDA. CARB-X is dedicated to accelerating the development of innovative antibacterial products from target/candidate identification and characterization through Phase I clinical trials. CARB-X is currently supporting 29 therapeutic candidates, including 11 new classes of antibiotics, as well as 6 diagnostics products. To facilitate the discovery and development of promising therapeutic candidates, NIAID provides unique no-cost preclinical and clinical services that include screening tests for antimicrobial activity and access to research reagents to assist in product testing. Additionally, NIAID supported preclinical development and first-in-human Phase I clinical testing of VNRX-5133, a novel beta-lactamase inhibitor (BLI). VNRX-5133 is the first BLI in clinical development that inhibits all known classes of beta-lactamases bacterial enzymes involved in resistance to the beta- lactam class of broad-spectrum antibiotics such as penicillin.

NIAID continues to support the development of antibacterial products in collaboration with academia, industry, and federal partners. A concerted research effort is required to combat the growing public health threat of antibiotic resistance. NIAID remains committed to facilitating the development of new antibiotics by supporting innovative research and offsetting the development costs of industry and academia.

GREG WALDEN, OREGON
CHAIRMAN

FRANK PALLONE, JR., NEW JERSEY
RANKING MEMBER
ONE HUNDRED FIFTEENTH CONGRESS
Congress of the United States
House of Representatives
Committee on Energy and Commerce
2125 Rayburn House Office Building
WASHINGTON, DC 20515-6115

July 12, 2018

Rear Admiral Denise Hinton
Chief Scientist
U.S. Food and Drug Administration
10903 New Hampshire Avenue
Silver Spring, MD 20993

Dear Admiral Hinton:

Thank you for appearing before the Subcommittee on Oversight and Investigations on June 15, 2018, to testify at the hearing entitled "The State of U.S. Public Health Biopreparedness: Responding to Biological Attacks, Pandemics, and Emerging Disease Outbreaks."

Pursuant to the Rules of the Committee on Energy and Commerce, the hearing record remains open for ten business days to permit Members to submit additional questions for the record, which are attached. To facilitate the printing of the hearing record, please respond to these questions with a transmittal letter by the close of business on Thursday, July 26, 2018. Your responses should be mailed to Ali Fulling, Legislative Clerk, Committee on Energy and Commerce, 2125 Rayburn House Office Building, Washington, DC 20515 and e-mailed in Word format to Ali.Fulling@mail.house.gov.

Thank you again for your time and effort preparing and delivering testimony before the Subcommittee.

Sincerely, Gregg Harper
Chairman
Subcommittee on Oversight and Investigations

cc: The Honorable Diana DeGette, Ranking Member, Subcommittee on Oversight and Investigations
Attachment

ATTACHMENT-ADDITIONAL QUESTIONS FOR THE RECORD

The Honorable Gregg Harper

I. Medical countermeasure (MCM) development can be a costly, time-consuming venture for the private sector. It is often one of the reasons why companies are reluctant to enter the MCM product space. How could the FDA provide better guidance and get involved earlier in the development process to help reduce this burden?

The Honorable Michael C. Burgess

I. Pharmaceutical companies face economic barriers to discovering and developing urgently needed new antibiotics to address drug resistant infections. I was encouraged by Commissioner Gottlieb's announcement earlier this week that FDA is working with CMS and other agencies to develop new payment models that would incentivize antibiotic research and development and the appropriate use of new antibiotics. Can you describe how these new models may work? Does Congress need to provide additional authorities or resources?

The Honorable Frank Pallone, Jr.

1. When a crisis does occur, what can FDA do to fast-track approval of countermeasures like vaccines and therapeutics?

2. How have GAIN and ADAPT helped FDA to incentivize antibiotic development in the private sector?

Chapter 489

**FACING 21ST CENTURY PUBLIC HEALTH THREATS:
OUR NATION’S PREPAREDNESS AND RESPONSE
CAPABILITIES, PART I***

Committee on Health, Education, Labor, and Pensions

Wednesday, January 17, 2018

U.S. Senate, Committee on Health, Education, Labor, and Pensions,
Washington, DC.

The Committee met, pursuant to notice, at 10:04 a.m. in room SD–430, Dirksen Senate Office Building, Hon. Richard Burr, presiding.

Present: Senators Alexander, Burr [presiding], Isakson, Collins, Cassidy, Young, Murkowski, Murray, Casey, Bennet, Murphy, Warren, Kaine, Hassan, Smith, and Jones.

OPENING STATEMENT OF SENATOR BURR

Senator Burr [presiding]. I would like to call this hearing to order, the Senate Health, Education, Labor, and Pensions Committee.

This morning, we are holding a hearing titled, “Facing the 21st Century Public Health Threats: Our Nation’s Preparedness and Response Capabilities.” We will hear from Dr. Robert Kadlec, the Assistant Secretary for Preparedness and Response at the Department of Health and Human Services; Dr. Stephen Redd, Director of the Office of Public Health Preparedness and Response at the Centers for Disease Control and Prevention; and Dr. Scott Gottlieb, Commissioner of the Food and Drug Administration.

* This is an edited, reformatted and augmented version of Hearing of the Committee on Health, Education, Labor, and Pensions, United States Senate, One Hundred Fifteenth Congress, Second Session, Publication No. S. HRG. 115–712, dated January 17, 2018.

This is the first of two hearings we plan to have on this topic. The second will be noticed for Tuesday, January 23.

Senator Murray and I each have an opening statement, then I am going to turn to Senator Alexander and Senator Casey for any opening remarks they might have. After that, we will introduce our panel of witnesses and hear their testimonies. And then each Member will have up to 5 minutes for any remarks and questions.

First, I would like to welcome the Chairman and thank him for giving me the opportunity to hold the gavel today. This hearing discusses a topic that is critical to our national security and has seen many years of bipartisan work in this Committee and in this Congress.

Together, we have developed and strengthened the framework to ensure we are prepared for chemical, biologic, radiological, and other nuclear threats with the potential to jeopardize the health of all Americans.

The Pandemic and All-Hazards Preparedness Act of 2006 created a framework which has grown and changed as we have learned from each public health experience we have been through. We should be proud of the accomplishments under PAHPA and the progress made over the last decade.

Our work has resulted in strong partnerships with our states and local counterparts, created greater certainty and accountability to bring forward medical countermeasures, and established a clear strategy with which we can combat the full range of public health threats we face today and those we may encounter in the future. Despite this progress, we are not fully prepared and more work remains to accomplish our goals. The Blue Ribbon Study Panel on Biodefense stated in their 2015 report that there are, and I quote, “Serious gaps and inadequacies that continue to leave the Nation vulnerable to threats from nature and terrorists alike.”

As we move forward in revisiting this successful and bipartisan law, I want to make it very clear to my colleagues that this is a reauthorization of a national security bill, and I look forward to working with each of you on this important issue.

The threats we face continue to evolve and it is critical that we bring, with this discussion, the vigilance, urgency, and resolve this mission demands. We are in an unprecedented era of technological and biomedical innovation and advancement.

In November 2016, the President’s Advisory Council on Science and Technology warned that, and I quote, “While the ongoing growth of biotechnology is a great boon for society, it also holds serious potential for destructive use by both states and technically competent individuals.”

I urge the U.S. Government’s past ways of thinking and organizing to meet biological threats needs to change to reflect and address this rapidly developing landscape. For this reason, it is critical that fostering and advancing innovation, particularly in the development of medical countermeasures, is top of mind and that we work through this reauthorization process to ensure CDC, FDA, ASPR, BARDA have what they need to keep pace with these rapidly changing and evolving threats.

This Committee has worked to push the Federal Government, and HHS in particular, to meet these challenges. An HHS that fosters innovation in the development of medical countermeasures and across PAHPA’s framework provides the greatest hope to ensure the safety of the American people. The witnesses we have before us today will be able to provide insight into the urgency of this mission and the promise innovation holds if properly leveraged.

I look forward to hearing from each of you about the progress that we have made, and where we can continue to improve policies and programs to realize their full potential to save Americans' lives.

Now, I would like to turn to Senator Murray for any comments she might have.

STATEMENT OF SENATOR MURRAY

Senator MURRAY. Thank you very much.

And thank you, to all of you, for joining this hearing on our Nation's preparedness to combat public health threats as we look toward now reauthorizing the Pandemic and All-Hazards Preparedness Act later this year.

I especially want to thank Senator Casey and Senator Burr for their bipartisan work and leadership on this really important issue. Local Washington state papers show why today's discussion is so important to families across this country. We have headlines like, "Flu Deaths And Cases Increasing In Pierce County." And, "Flu Outbreak In Snohomish County Kills Five; 50 Hospitalized."

A bad flu season can be a nightmare for families and too often ends in horrible tragedy. Just as we must continue to improve our public health response across the board to prevent those tragedies on the local level, we have to also make sure we are vigilant against pandemics of a global scale.

A pandemic could affect half a billion people, more than the entire population of the United States; and that is not speculation. It happened 100 years ago. The 1918 influenza epidemic was a tragedy more deadly to the human race than World War I. And today, the threat of pandemic flu is joined by new threats.

What have we learned in the last century? Are we better prepared for the next catastrophe?

When we consider Ebola and how the Centers for Disease Control and Prevention, and so many partners, supported Nigeria as they instituted evidence-based policies and tracked the path of that disease, and contained it when the outbreak reached Lagos, the answer is clearly, yes.

When you consider our Strategic National Stockpile which can deliver 50 tons of emergency medical supplies anywhere in the U.S. in 12 hours, the answer is clearly, yes.

When you consider the FDA's approval of new medical counter- measures to combat anthrax, and flu, and radiation, and plague, the answer is clearly, yes.

However, our track record is far from perfect. We still can do better.

We can do better than the President's way too slow response in Puerto Rico and the U.S. Virgin Islands after Hurricane Maria. The storm left many Americans without access to clean water, and electricity, and healthcare for months.

We can do better than the Administration's response to the opioid epidemic. President Trump declared the crisis a public health emergency 83 days ago and has taken little meaningful action since.

So I am glad this Committee will continue its bipartisan work to address the opioid crisis in another hearing soon.

We can also do better than our slow response in approving funding to combat Zika in 2016. The World Health Organization declared Zika a global health emergency in February. Instead of a fast response with needed funding, the response got politicized around some Republicans who pushed to undermine women's healthcare and access to contraception, which was a key requirement to prevent the virus from causing devastating birth defects. As a result, that took Congress 9 months to pass emergency funding for a public health crisis that endangered mothers, and babies, and families across the world. That delay hurt people and it harmed families in ways they are going to carry for the rest of their lives. So we have to do better.

We are most successful at protecting our families against pandemic threats when we respond with quick, bipartisan action.

We need decisions based in science and expert medical opinion, not ideology, especially when it comes to women's health.

We need Federal, state, and local agencies to hire the people, and capacity, and have the funding they need to protect communities. Hiring freezes and funding cuts make us less prepared, not more. We need to plan for everyone. We cannot overlook the young or the elderly. We cannot forget pregnant women, or individuals with disabilities, or those fighting chronic diseases like diabetes.

We need innovative medical countermeasures to protect us from today's threats like a universal flu vaccine and antibiotics to combat resistant bacteria. And we must continue strong partnerships with industry that will allow us to rapidly respond to new threats. We need to stop fear and uncertainty before they create panic by getting families helpful and accurate information from sources that they trust. We cannot allow anyone to undermine the science of proven solutions like vaccines.

We need to respond to global health crises abroad before they travel here to home. Diseases are not stopped by borders, or walls, or bans. This is a place where the United States can, and should, lead.

We should continue to show our international partners that we are focused on these issues and will be their ally in preparing for, and addressing, public health threats.

Congress has a strong, bipartisan track record of addressing these challenges through the PAHPA, which strengthened our Nation's public health preparedness and created new roles, and programs, and authorities for public health emergency response.

Reauthorizing the Act in 2013, we built on that record and enhanced medical surge capacity. We modernized biosurveillance capabilities and increased our focus on at risk individuals.

I am hopeful we can continue that progress with legislation that focuses on the science and evidence based policies we know work to mitigate public health crises, that considers the needs of everyone, and puts families and women before politics, supports state and local public health officials, ensures communities do not spend months waiting for emergency resources, and enables us to respond to the next crisis with foresight rather than learn from the next tragedy with hindsight.

We do not know what the next public health threat will be. We do not know where, or when, or even how it will start. But we do know that being prepared starts now.

All of you here today have a critical role to play in keeping our communities healthy and safe. The Food and Drug Administration helps facilitate the development and review of

medical counter-measures and grants emergency use authorizations for products that are needed on the frontlines.

The Assistant Secretary of Preparedness and Response guides our Nation's preparedness planning. They help ensure our healthcare system is ready to face any emergency. And it invests

in the medical countermeasures pipeline through biomedical advanced research and development authority.

The Centers for Disease Control and Prevention is on the frontlines supporting state and local public health departments, overseeing the Strategic National Stockpile, gathering and analyzing key data, and serving as a trusted source of information to the public.

I am interested to hear from all of you today about your work to fulfill these important roles and keep our country safe.

Mr. Chairman, I do want to say I am frustrated that Director Fitzgerald is, once again, unable to join us here today. Due to conflicts of interest presented by investments, our CDC Director still has to recuse herself on some of the important health issues that we face, including issues related to data collection and information sharing, which are very relevant to the conversation that we are having today. I am concerned that she still cannot give her full attention to all the pressing health threats we face and hope that these conflicts of interest will be resolved soon.

Thank you, Dr. Redd, for joining us in her place and I look forward to hearing from you.

Thank you, Mr. Chairman.

Senator BURR. Thanks, Senator Murray. Senator Alexander.

STATEMENT OF SENATOR ALEXANDER

The CHAIRMAN. Thank you, Senator Burr.

Senator Burr, thank you for your willingness to chair this hearing.

In March 2013, President Obama signed into law the bipartisan Pandemic and All-Hazards Preparedness Reauthorization Act. Senator Burr was the author of that reauthorization and the original legislation, which became law in 2006. He worked with many Senators on this Committee, both Democratic and Republican, and I thank them all for that. Senator Murray, Senator Casey, and others, Senator Isakson was another of those. So Senator Burr is chairing the hearing and I thank him for that.

I would also like to welcome Senator Smith from Minnesota, who is joining our Committee and replacing Senator Franken, who was a valuable Member of the Committee.

Senator Jones, from Alabama, is also a new Member of the Committee. We welcome him. He replaced Senator Whitehouse, who was a very valuable Member of the Committee, and who has taken a lesser assignment on the Finance Committee for some reason.

[Laughter.]

The CHAIRMAN. But we will miss Sheldon and his work on this Committee.

Mr. Chairman, I am going to withhold my comments, although what I would like to do is call on Senator Isakson for 1 minute, just to make some comments, and then we will go to Senator Casey.

Senator BURR. Senator Isakson.

Senator ISAKSON. Thank you, Mr. Chairman.

I just wanted to, in reference to the statements made by the ranking Member, Senator Murray, whom I have talked to about Dr. Fitzgerald. I talked with Dr. Fitzgerald yesterday.

As chairman of the Ethics Committee, I have gotten her in touch with the appropriate people to deal with the issue. She is forthrightly dealing with it to the best I can determine and I am working expeditiously to see we get it done as quickly as possible, so she will not have any conflict to testify whatsoever. And that is her desire as well.

Thank you.

Senator BURR. Senator Casey.

STATEMENT OF SENATOR CASEY

Senator CASEY. Thank you very much, Senator Burr.

I am grateful for this hearing, and grateful to be working with you again on this reauthorization, and commend your work on this for many, many years.

I also want to thank, of course, the Chairman, Chairman Alexander and Ranking Member Murray for this bipartisan hearing on the Nation's preparedness and response capabilities in advance of the reauthorization of the Pandemic and All-Hazards Preparedness Act known as PAHPA.

I will give you one story, one brief story, but I think, instructive about how important preparation is. This is a good example of preparedness infrastructure that PAHPA supports, in this case, in the aftermath of a tragedy, a train derailment that occurred in Philadelphia in May 2015.

The train was carrying 238 passengers. When it derailed, eight people lost their lives. Over 200 were injured in that derailment. Fortunately, through funding from PAHPA's Hospital Preparedness Program, which we know by the acronym HPP, the Pennsylvania Department of Health and a regional healthcare coalition had long been working together to prepare local healthcare systems for emergencies that could cause a surge in patients.

When the train derailed, HPP funded systems were tracking bed availability in local hospitals and providing that information in real time to emergency responders who were at the scene, helping them to effectively triage patients, send them to hospitals that had the capacity to accept additional patients so they could begin to receive the care they needed.

Because these systems were in place before the train derailed, they were ready to protect both health and to save lives when seconds, literally seconds, counted.

Yet, health security threats are increasing in frequency and intensity due to a combination of factors including newly emerging infectious diseases, extreme weather events, and our aging infrastructure.

So now, more than ever, we must continue to build our Nation's resiliency by investing in countermeasure development, surveillance, and supporting state and local partners to reduce the impact of health events in the country.

So I would like to thank today's witnesses for their service. It is important to mention your service to the country, as well as your commitment to protecting America's public health.

We look forward to the hearing and grateful for the work that we can do today at this hearing.

Thank you, Mr. Chairman.

Senator BURR. Senator Casey, thank you.

Thank you for your continued help and work on this issue.

Let me just remind Members that this is the start of the reauthorization of PAHPA. Now, having been in Congress for 24 years, I realize that when you get involved in HHS legislation and FDA legislation, there is always a temptation to fix other things.

I want to encourage you to fight the urge. Let us keep this focused on perfecting PAHPA. It has been successful. We still have work to do, but if we become distracted and create a fight over changes within the FDA that have nothing related to this, or HHS, or somewhere else because the sheer geography that just PAHPA allows us to get into, we will lose the focus of what we are doing, and that is trying to make PAHPA even more effective in the future.

So with that, I would like to introduce our witnesses, which each have up to 5 minutes to give their testimony.

I am pleased to welcome today Dr. Robert Kadlec. Dr. Kadlec is the Assistant Secretary for Preparedness and Response at the Department of Health and Human Services. If he does not like the title, he was the one that created it.

It was with Dr. Kadlec's help that we created the ASPR position as part of PAHPA to establish a clear line of authority in the event of a public health emergency. The APSR is the person at HHS solely responsible for leading and coordinating the Federal medical and public health preparedness and response effort across all the agencies within HHS including FDA and CDC.

Dr. Bob, delighted to have you back today.

Next, we will hear from Dr. Scott Gottlieb. Dr. Gottlieb is the Commissioner of the Food and Drug Administration.

The FDA plays a critical role in our emergency preparedness and response capabilities through its review of medical countermeasures, including drugs, vaccines, diagnostic tests, and by ensuring these countermeasures are safe and effective.

Further, the 2013 reauthorization of PAHPA aimed to improve regulatory certainty and predictability for medical countermeasures under review at the FDA, while also providing the agency with the additional authorities to support rapid response to public health emergencies.

Scott, we are delighted to have you here and delighted to have you in that position at FDA.

Finally, we will hear from Dr. Stephen Redd. Dr. Redd is the Director of the Office of Public Health Preparedness and Response at the Centers for Disease Control and Prevention.

The CDC serves a number of roles under the PAHPA framework and has built strong relationships with state and local public health departments, an important aspect of preparing for, and responding to, emergency public health threats.

The CDC also works to make sure we have the information we need in advance of and during a public health emergency. As part of this effort, the CDC houses an expansive epidemiology laboratory capacity and is responsible for biosurveillance and public health data collection activities.

Again, we welcome all of you.

Let me just say at the beginning, I believe the hurdle that is in our way is not available innovation. I believe the hurdle that is in our way is government. Clearly defining what it is that our need is, and the certainty of a pathway for getting the approvals that we need for those to actually be deployed.

So I hope you will keep those in mind as you go through, not just your testimony, your questions, but more importantly in the roles that you carry out after leaving. Understand that you are on the frontlines at making this happen.

Dr. Bob, the floor is yours.

**STATEMENT OF ROBERT KADLEC, M.D., ASSISTANT SECRETARY
FOR PREPAREDNESS AND RESPONSE, DEPARTMENT OF HEALTH
AND HUMAN SERVICES, WASHINGTON, DC**

Dr. KADLEC. Well, thank you, sir. Sorry for the false start there. I was excited to be here, sir. I was ready to go.

Good morning, Mr. Chairman, both of you, sirs and Senator Murray, and distinguished Members of the Committee.

I assumed this role 5 months ago just a week before Hurricane Harvey struck Texas. It has been an interesting experience so far and I have much to share from that experience.

I appreciate the opportunity to appear before you today as you prepare to consider the second reauthorization of PAHPA. This Committee championed the bipartisan effort to draft and pass this groundbreaking legislation and I want to thank you for your continuing commitment to this endeavor.

I am proud to have played a part in the original legislative process during my tenure with this Committee, and acknowledge the vision and leadership of Senator Burr and the late Senator Ted Kennedy.

This morning, I will share with you my perspective on the national security imperative of PAHPA, the mission and duties of ASPR, and my vision for areas of improvement.

The Constitution states that one of the Federal Government's fundamental obligations is to provide for the common defense, to protect the American people, our homeland, and our way of life. The strength of our Nation's public health and medical infrastructure, as well as the capabilities to quickly mobilize a coordinated national response to pandemics, attacks, and disasters are essential to save lives and protect all Americans.

Therefore, improving national readiness and response capabilities for 21st century threats is a national security imperative, as Senator Burr outlined earlier, and is the crux of my efforts as the ASPR.

The 21st century health security environment is increasingly complex and dangerous. It demands that we react with urgency. Having recently left my job with the Senate Select Committee on Intelligence, I know these threats all too well.

Terrorist organizations remain determined to attack the United States. State actors now directly threaten our homeland with nuclear weapons and have the means to employ both chemical and biological weapons.

Further, we have witnessed the increased frequency of naturally occurring disasters as well as disease outbreaks and are currently monitoring potential emerging infectious diseases that could cause a pandemic such as the H7N9 influenza strain circulating in China.

The bottom line is whatever happens, your constituents, the American people, expect our Federal Government to be ready to respond to save lives.

When APSR was originally established by PAHPA a decade ago, the objective was to answer a simple question: who is in charge of all Federal public health and medical preparedness and response functions? The approach adopted was based on the Goldwater-Nichols Act that created the Unified Combatant Commands at the Department of Defense.

APSR's mission is to save lives and protect Americans from these threats by recruiting the entire weight of the federal, medical, and public health assets and recruit support of the public health sector to support state and local activities and responses to help Americans in distress.

As APSR, I have four key priorities.

First, provide strong leadership. Focus on coordination, planning, and preparing for events that threaten the national health security.

Second, develop the national disaster healthcare system.

Third, advocate for CDC's sustainment of a robust and reliable public health security capabilities.

Last, but certainly not least, advance an innovative medical countermeasure enterprise.

Two areas of progress and opportunity I will elaborate on are operational healthcare readiness capacity and the medical counter- measures enterprise.

The importance of the national healthcare readiness and medical surge capacity was highlighted during this hurricane season. After Hurricanes Harvey, Irma, and Maria, ASPR led federal medical and public health response and recovery activities under the national response framework. We worked closely with FEMA, and state, and territorial health officials to augment healthcare with HHS disaster medical assistance teams, as well as V.A. and DOD assets.

We learned from these disasters that ASPR needs to update its incident command and deployable medical capabilities, as well as enhance our support for the healthcare infrastructure across the country.

As with medical countermeasures, the Nation's healthcare delivery infrastructure is mostly a private sector enterprise that must be effectively engaged in improving readiness.

To address the potential catastrophic medical consequences of the 21st century threats, we need a tiered regional system that is based on existing local healthcare coalitions and trauma centers that integrates all medical response capabilities, including Federal assets, as well as emergency medical services, the frontline of our response capabilities.

We must expand specialty care expertise and trauma, behavioral healthcare and chemical, biological, radiological nuclear response. And certainly, but not least, incentivize the healthcare system to integrate measures of preparedness into daily standards of care. I call this the foundation of a national disaster healthcare system.

The second area is our medical countermeasure enterprise, and I am grateful that Dr. Rick Bright behind me—Rick, why do you not wave to the crowd—who is the Director of BARDA, is joining me today.

BARDA was established as part of PAHPA and is a component of ASPR to bridge the so-called “valley of death” in the late stage development of vaccine, drug, and diagnostic development when many products historically languished or failed.

By using flexible, nimble authorities, multiyear advanced funding, strong public-private partnerships, and cutting edge expertise BARDA has successfully pushed many innovative products from advanced development to stockpiling FDA approval. To this date, 34 products have been approved by the FDA for the purposes of responding to disasters to the credit of Dr. Bright and his predecessor, Dr. Robin Robinson and the team at BARDA.

We have opportunities to further improve this enterprise by streamlining our internal decision-making processes, finding new ways to support innovation, promoting flexible, fast response capabilities, and increasing our collaboration with Federal interagency partners.

We also must work closely with our state and local partners, as well as the private sector to enhance the capability to quickly distribute and dispense medical countermeasures in an emergency.

In times of great challenge, we have the opportunity to build on the great progress made and further improve our national readiness and response capabilities.

I look forward to working with you and your staff. And thank you, again, for your bipartisan support and commitment to national security.

I am happy to answer any questions you have. [The prepared statement of Dr. Kadlec follows:]

PREPARED STATEMENT OF ROBERT KADLEC

Good morning Mr. Chairman, Senator Murray, and other distinguished Members of the Committee. I am Dr. Bob Kadlec, the Assistant Secretary for Preparedness and Response (ASPR) at the Department of Health and Human Services (HHS). I assumed this role 5 months ago, a week before hurricane Harvey struck Texas. I appreciate the opportunity to appear before you today as you prepare to consider the second reauthorization of the Pandemic and All-Hazards Preparedness Act (PAHPA), which expires at the end of this fiscal year.

Building upon years of incremental legislative changes in the prior decade, this seminal legislation transformed the Federal Government’s medical and public health preparedness for threats to our national security. This Committee championed the bipartisan oversight and analysis that led to the drafting and passage of this groundbreaking legislation. I want to thank you for continuing that commitment here today.

I am proud to have played a part in that original legislative process, when during the 109th Congress, I was Staff Director of this Committee’s Subcommittee on Bioterrorism and Public Health Preparedness, led by Senators Burr and Kennedy. In the decades before and after PAHPA was passed, I worked in various government capacities focused on biodefense and national security. I spent more than 20 years in the United States Air Force as an officer and physician, and served as Special Advisor for Counter Proliferation Policy within the Office of the Secretary of Defense during 9/11 and the 2001 anthrax attacks. I served two tours of duty at the White House Homeland Security Council, first as the Director for Biodefense then as Special Assistant to President Bush for Biodefense Policy from 2007 to

2009. Most recently before taking my current position, I served as the Deputy Staff Director for the Senate Select Committee on Intelligence.

This morning, I will share with you my perspective on the national security imperative of PAHPA, the mission and duties of ASPR, the status of our Department and our Nation's public health and medical preparedness and response capabilities, and my vision for areas of improvement. I welcome the opportunity to engage with you and your staff in the months ahead as you continue your oversight and legislative drafting.

The National Security Imperative

The Constitution states that one of the Federal Government's fundamental responsibilities is to provide for the common defense—to protect the American people, our homeland, and our way of life. The strength of our Nation's public health and medical infrastructure, and the capabilities necessary to quickly mobilize a coordinated national response to emergencies and disasters, are foundational for the quality of life of our citizens and vital to our national security. Therefore, improving national readiness and response capabilities for 21st century health security threats is a national security imperative and is my singular focus as the ASPR.

The 21st century health security environment is increasingly complex and dangerous; it demands that we act with urgency and singular effort: to save lives and protect Americans. Terrorist organizations such as ISIS and al-Qaida remain determined to attack the United States as we experienced first-hand in 2001. ISIS has demonstrated no compunction about using chemical and other unconventional weapons in attacks overseas. State actors, such as North Korea, have already threatened our homeland with nuclear weapons, and have the means to employ both chemical and biological weapons; the Syrian regime has already used chemical weapons against its own citizens.

Furthermore, we have witnessed the impacts of naturally occurring outbreaks such as influenza, Ebola, and SARS, and we are monitoring other potential emerging infectious diseases that could cause a pandemic, such as the H7N9 influenza strain circulating in China. 2018 marks the 100 year anniversary of the 1918 influenza pandemic, which killed more people than World War I. During that pandemic, more than 25 percent of the U.S. population became sick and 675,000 Americans, many of them young, healthy adults, died from the highly virulent influenza virus. Cyber-attacks like the WannaCry incident remind us that technological advancements have tradeoffs in the form of new vulnerabilities and risks, as our health delivery systems become more networked.

Finally, we face extreme weather events, such as the recent 2017 hurricane season in which Hurricanes Harvey, Irma, and Maria caused an unprecedented amount of damage, reminding us of the awesome destructive power of nature.

These are threats that most of us would rather not think about. However, when natural disasters, disease outbreaks, or attacks occur, the people expect our government to be ready to respond to save lives and protect Americans.

The ASPR Mission and Duties

When ASPR was originally established by PAHPA a decade ago, the objective was to create “unity of command” by consolidating all Federal nonmilitary public health and medical preparedness and response functions under the ASPR. This approach was modeled on the Goldwater-Nichols Act that created the Department of Defense (DoD) combatant commands; the impetus was the disorganized and fragmented response to Hurricane Katrina in 2005.

ASPR’s mission is to save lives and protect Americans from 21st century health security threats. ASPR is, in effect, the national security mission manager for HHS. As such, on behalf of the Secretary of HHS, ASPR leads the public health and medical, preparedness, response and recovery to disasters and public health emergencies, in accordance with the National Response Framework (NRF) and Emergency Support Function No. 8 (Public Health and Medical Services). It is my responsibility to coordinate the Nation’s medical and public health capabilities to help Americans during such events, whatever their cause. ASPR also coordinates with other components of HHS with respect to HHS’s role in ESF No. 6 (Mass Care, Housing, and Human Services) and HHS’s lead role as the coordinating agency with respect to the Health and Social Services Recovery Support Function.

ASPR coordinates across HHS, the Federal interagency, and supports state, local, territorial, and tribal health partners in preparing for and responding to emergencies and disasters. ASPR, in partnership with HHS agencies, works to enhance medical surge capacity by organizing, training, equipping, and deploying Federal public health and medical personnel and providing logistical support for Federal responses to public health emergencies. ASPR supports readiness at the state and local level by coordinating Federal grants and cooperative agreements and carrying out drills and operational exercises. ASPR oversees advanced research, development, and procurement of medical countermeasures (e.g., vaccines, medicines, diagnostics, and other necessary medical supplies), and coordinates the stockpiling of such countermeasures. ASPR manages the Biomedical Advanced Research and Development Authority (BARDA), Project BioShield, and the Public Health Emergency Medical Countermeasures Enterprise.

HHS and ASPR have made significant progress since PAHPA was enacted in 2006 and was reauthorized in 2013, which I will discuss shortly. The ASPR organization is filled with very capable, committed, and mission-driven staff; I am proud to lead them. It is my goal to further improve national public health and medical readiness and response capabilities, which have been developed by my predecessors who worked long hours to establish ASPR and build the capabilities that exist today. I aim to do that through four key priority areas:

First, provide strong leadership, including clear policy direction, improved threat awareness, and secure adequate resources.

Second, seek the creation of a “national disaster healthcare system” by better leveraging and enhancing existing programs—such as the Hospital Preparedness Program (HPP) and the National Disaster Medical System (NDMS)—to create a more coherent, comprehensive, and capable regional system integrated into daily care delivery.

Third, advocate for the sustainment of robust and reliable public health security capabilities, primarily through the Centers for Disease Control and Prevention (CDC), but also through other components of HHS, including an improved ability to detect and diagnose

infectious diseases and other threats, as well as the capability to rapidly dispense medical countermeasures in an emergency.

Fourth, advance an innovative medical countermeasures enterprise by capitalizing on additional authorities provided in the 21st Century Cures Act, as well as advances in biotechnology and science, in order to develop and maintain a robust stockpile of safe and efficacious vaccines, medicines, and supplies to respond to emerging disease outbreaks, pandemics, and chemical, biological, radiological, and nuclear incidents and attacks.

The State of Public Health and Medical Preparedness and Response Capabilities

In 2006, when then Secretary of Health and Human Services Michael Leavitt testified before this Committee in advance of PAHPA's passage, he told Senators that we had the ability to "become the first generation in history to be prepared for a possible pandemic." At that time, HHS was closely watching the H5N1 influenza virus, and was concerned about the potential for another human influenza pandemic. Congress invested heavily by passing emergency supplemental appropriations bills, which were used to greatly expand our domestic vaccine manufacturing infrastructure, invest in new vaccine development, and provide funding to state and local governments to enhance medical and public health readiness.

Today, our capabilities are far greater than they were then; for example, we have sufficient domestic vaccine manufacturing capacity to produce bulk vaccine for every American within 6 months. However, we have exhausted the emergency supplemental funding balances at a time when we are now closely watching the H7N9 influenza virus circulating in China, and we are concerned with the ominous trends that we are seeing. While building domestic manufacturing capacity may be a onetime expenditure, maintaining that capacity as well as sustaining, testing, and strengthening the readiness of our medical and public health infrastructure at the state and local level requires continuous support and an enduring commitment to the Public Health Emergency Medical Countermeasures Enterprise.

Last month, a report by the public health organization Trust for America's Health found that half of states scored five or lower out of 10 on health emergency preparedness. Earlier in 2016, the National Health Security Preparedness Index from the Robert Wood Johnson Foundation found that health security metrics showed modest 1.5 percent improvement overall during 2016, reaching the highest level of out of 10 total; however, levels of readiness varied significantly across the country. So, while we have made progress in the last decade, we still have work to do. Two areas of progress and opportunities I would like to highlight are our medical countermeasures enterprise, specifically BARDA, and our healthcare readiness capacity.

Medical Countermeasures Enterprise—BARDA

PAHPA established BARDA to bridge the so-called "valley of death" in late stage development of medical countermeasures where many products historically languished or

failed. By using flexible, nimble authorities, multiyear advanced funding, strong public-private partnerships, and cutting edge expertise, BARDA has successfully pushed innovative medical countermeasures, such as vaccines, drugs, and diagnostics, through advanced development to stockpiling and FDA approval or licensing.

In the last decade, BARDA's strong partnerships with the National Institutes of Health, other HHS components, and biotechnology and pharmaceutical companies have led to 34 medical countermeasures approved or licensed by the FDA, which is a staggering accomplishment. BARDA has supported the development of 27 medical countermeasures against Department of Homeland Security (DHS) identified national security threats through Project BioShield, including products for smallpox, anthrax, botulinum, radiologic/nuclear emergencies, and chemical events. Fourteen of these products have been placed in the Strategic National Stockpile and are ready to be used in an emergency. BARDA also has supported the development of 23 influenza vaccines, antiviral drugs, devices, and diagnostics to address the risk of pandemic influenza. As a result of this progress, more medical countermeasures than ever before are eligible to be acquired for the SNS, thereby creating new challenges in terms of acquiring and maintaining sufficient quantities of medical countermeasures for identified threats.

We are supporting the development and stockpiling of many more novel medical countermeasures within the next few years, such as H7N9 influenza vaccines, next generation anthrax vaccines, enhanced smallpox vaccines, biodosimetry diagnostic devices, thermal burn radiation drug and skin replacement therapies, radiation cell therapies, new antibiotics, and new chemical antidotes.

We also have opportunities to further improve our national security medical countermeasures enterprise by streamlining our internal decision-making processes, finding new ways to support innovation, promoting flexible, fast response capabilities, and increasing our collaboration with Federal interagency partners, such as DoD and Department of Veterans Affairs (VA). We also must work closely with our state, local, territorial, and tribal partners, as well as the private sector to enhance the capability to quickly distribute and dispense medical countermeasures in an emergency—if we can't get these products to the right place, at the right time, then the enterprise has failed.

Healthcare Readiness to Respond

The 2017 hurricane season highlighted the importance of national healthcare readiness and medical surge capacity. ASPR led the public health and medical responses to Hurricanes Harvey, Irma, and Maria under the National Response Framework Emergency Support Function No. 8 mission. We worked closely with state and territory health officials in affected areas to augment care with NDMS teams, VA personnel and facility support, and DoD transportation, facilities, and clinicians. Personnel under the supervision of HHS treated over 36,000 patients, and HHS deployed over 4,500 personnel, evacuated nearly 800 patients, awarded over 200 contracts, and provided nearly 950 tons of equipment.

During the response, due to the combined efforts of ASPR and the Centers for Medicare & Medicaid Services (CMS), we utilized the innovative HHS emPOWER program to identify and treat at risk individuals requiring electricity-dependent medical and assistive equipment

(e.g., ventilators, oxygen concentrators, feeding machines, intravenous infusion pumps, suction pumps, dialysis machines, wheelchairs). In one instance, ASPR teams used this data and worked with Urban Search and Rescue teams to identify all of the dialysis patients in the U.S. Virgin Islands and evacuate those patients for treatment since the local dialysis centers were destroyed. Despite our successes, we also learned that ASPR needs to improve its internal capabilities as well as enhance our support for the healthcare infrastructure across the country. As with medical countermeasures, the Nation's healthcare delivery infrastructure is mostly a private sector enterprise. We must better leverage and enhance existing Federal programs—such as the Hospital Preparedness Program and NDMS—to create a more coherent, comprehensive, and capable regional system integrated into daily care delivery I call this the foundation of a “national disaster healthcare system.”

Conclusion

Through this second reauthorization of PAHPA, we have the opportunity to build on the great progress made and further improve our national readiness and response capabilities for 21st century health security threats. The Department looks forward to working with you in the months ahead to consider any legislative changes needed to achieve this objective. I am committing the entire ASPR team's grit, ingenuity, expertise, and perseverance to this mission. Thank you, again, for your bipartisan commitment to this national security imperative, and I look forward to continuing to work together to enhance our Nation's health security. I am happy to answer any questions you may have.

Senator BURR. Thank you, Dr. Bob. Dr. Gottlieb.

STATEMENT OF SCOTT GOTTLIEB, M.D., COMMISSIONER, U.S. FOOD AND DRUG ADMINISTRATION, SILVER SPRING, MD

Dr. GOTTLIEB. Senator Burr, Ranking Member Murray, and Members of the Committee.

Thank you for the invitation to testify today about genome editing technology.

Our Nation has faced many emerging public health challenges and unfortunately, will face additional challenges in the future. Thankfully, our preparedness and the ability to respond to such challenges has improved greatly since the original enactment of the Pandemic and All-Hazards Preparedness Act.

Each emergency is unique. Many are the result of emerging infectious threats, but the technology for manipulating science for diabolical purposes is becoming more ubiquitous and widely understood. So we face new and pervasive risks.

2017 was marked by the risks posed by several extreme natural disasters, which caused significant devastation and human suffering. These tragedies tested our Nation's capabilities to respond. Today, I am going to focus my remarks on the impact of these storms on medical products manufactured in Puerto Rico and the actions we are taking to mitigate existing and potential product shortages.

The impact of Hurricane Maria showed the importance of Puerto Rico to our medical product manufacturing base, as well as the intricate and sometimes fragile nature of that supply chain.

I want to focus on the complexities of the saline shortage because it has stressed our system and I know that many of you are deeply and rightly concerned by this situation.

Saline solution has been in and out of shortage for several years. There are only a small number of primary manufacturers. So when one manufacturer lowers production, even for routine maintenance, there is stress on the entire system.

One of the largest manufacturers of I.V. saline is Baxter, and their primary sites for small volume bags are located in Puerto Rico. These sites struggled to regain power and return to full capacity following the storm when roads to some of the manufacturing plants were disabled.

We worked closely with Baxter in partnership with the Department of Homeland Security, and Puerto Rico authorities, and Bob—so thank you for your support, as well—to ensure that they were able to get back on the power grid on a priority basis to stabilize production.

We also worked with various saline manufacturers to find other manufacturing facilities globally that could help supply the U.S. until Baxter's Puerto Rico location was back up and running and the shortage was addressed.

To mitigate that shortage, we worked with manufacturers on the importation of saline from locations in Ireland, Australia, Mexico,

Canada, Germany, and most recently, Brazil. When we import from international facilities, generally, the manufacturers adjust their distribution to send some product to the U.S., but there is no actual increase in the total global production of product.

Baxter's manufacturing facilities in Puerto Rico are now stable and on the grid, although the power situation on the island is still fragile. We expect their return to normal production will improve the situation.

Before the storms hit, and in anticipation of the crisis, FDA also prioritized the approval of saline products by two manufacturers, Fresenius Kabi laboratories, and Grifols. Both should start production soon, and having these two additional manufacturers online will help increase the overall supply of saline produced and distributed in the U.S.

But this shortage has also had ripple effects. In order to find workarounds for the filled saline bags that were in shortage, providers have put various mitigation strategies in place. One strategy has hospitals compounding product themselves and this has caused an increased demand for empty i.v. bags. There have been signals indicating that this increased demand is putting pressure on the supply of empty i.v. bags. The FDA is taking steps to address that situation and determine which manufacturers could potentially increase capacity if necessary.

I have reached out to some of these medical device manufacturers personally to inquire about their capacity to increase production as demand for I.V. containers continues to increase.

The scope of the flu outbreak across the country has also added to the strain on this tight supply chain. The shortage, and the impact of the crisis in Puerto Rico, underscores the need to continuously elevate our preparedness.

There are going to be lessons learned from this episode, and already, we have made some key observations about our ability to detect device shortages. Since we lack authority to

require notification of device shortages, we have had to depend on manufacturers and distributors reaching out to the FDA or had to seek them out proactively.

Our work in the shortage situation is an example of how the FDA has reacted in response to emergency situations. At the same time, we continue to work hard to improve our regulatory clarity and predictability for the development of medical countermeasures. That is an essential component of our national preparedness strategy.

Today, we released draft guidance on Material Threat Medical Countermeasure and Priority Review Vouchers which explains how the FDA is implementing the PRV program to incentivize the development of certain drug and biologics medical countermeasures. I look forward to working with Congress to continue to increase our readiness for emergencies, and look forward to answering your questions today.

[The prepared statement of Dr. Gottlieb follows:]

PREPARED STATEMENT OF SCOTT GOTTLIEB

Chairman Alexander, Ranking Member Murray, and Members of the Committee, thank you for the opportunity to appear today to discuss reauthorization of the Pandemic and All-Hazards Preparedness Act (PAHPA). PAHPA, which was passed in 2006 and reauthorized in 2013, is a key piece of legislation that—along with other significant legislative achievements such as the Project BioShield Act of 2004, the Public Readiness and Emergency Preparedness (PREP) Act (2005), and the 21st Century Cures Act (Cures Act) enacted in 2016—has served to significantly strengthen our country’s preparedness for, and response to, public health emergencies involving chemical, biological, radiological, and nuclear (CBRN) threats as well as emerging infectious disease threats, such as the Zika virus and pandemic influenza.

The Pandemic and All-Hazards Preparedness Reauthorization Act of 2013 (PAHPRA), in particular, recognized the key role the Food and Drug Administration (FDA or the Agency) plays in emergency preparedness and response, and codified and built on FDA’s ongoing efforts to augment review processes and advance regulatory science to enable FDA to better respond to public health emergencies. The provisions in PAHPRA—as well as in the other key pieces of legislation I mentioned—have provided FDA with essential tools that continue to support us in our mission to protect and promote public health.

FDA’s Public Health Emergency Preparedness and Response Mission

FDA plays a critical role in facilitating preparedness for and response to CBRN and emerging infectious disease threats. These threats can and often do emerge without warning as was the case with the anthrax attacks of 2001, the 2009 H1N1 influenza pandemic, the 2014 Ebola outbreak in West Africa, as well as in the ongoing Zika virus outbreak.

FDA’s role in facilitating preparedness for, and response to, CBRN and emerging infectious disease threats focuses largely on facilitating the development and availability of medical countermeasures—such as vaccines, therapeutics, and diagnostic tests—to respond to these threats. FDA works closely with its HHS and other U.S. Government partners through the Public Health Emergency Medical Countermeasures Enterprise (PHEMCE), as well as with regulated industry and non-governmental organizations (NGO’s), to build and sustain

the medical countermeasure programs necessary to effectively respond to public health emergencies. FDA is also committed to working closely with the Department of Defense (DoD) to facilitate the development and availability of medical counter-measures to support the unique needs of our Nation's warfighters. The Agency is already actively implementing the legislation enacted at the end of last year to further prioritize this critical work with DoD. Senior leadership at the Agency is leading these efforts, and we look forward to keeping Congress informed of our progress in these critical areas.

FDA's Medical Countermeasures Initiative (MCMi)—established in 2010—brought additional resources to FDA that enabled FDA to hire additional expert staff and to become more deeply and thoroughly engaged in medical countermeasure activities. This program continues to be key to establishing clear regulatory pathways for medical countermeasures, advancing medical countermeasure regulatory science to support regulatory decisionmaking, and advancing important policies and mechanisms to facilitate the timely development and availability of medical counter-measures. FDA's goal is to be modern and efficient in its regulation of safe and effective medical products, and that includes medical countermeasures.

FDA's operations within its medical countermeasures mission cover a broad range of activities vital to facilitating the development of, and access to, safe and effective medical countermeasures, including:

- Reviewing medical countermeasure marketing applications and approving those that meet standards for safety and efficacy;
- Providing regulatory advice, guidance and technical assistance to sponsors developing medical countermeasures, as well as to U.S. Government partners, international regulators, and international organizations such as the World Health Organization;
- Supporting efforts to establish and sustain an adequate supply of medical countermeasures, including averting supply disruptions when feasible and, in certain situations, allowing products to be used beyond their expiration dates when supported by appropriate scientific evaluation;
- Enabling access to medical countermeasures that are not yet approved for use—when necessary—through an appropriate mechanism, including through FDA's Emergency Use Authorization (EUA) authority;
- Proactively identifying and resolving regulatory challenges associated with medical countermeasure development and ensuring that FDA regulations and policies adequately support medical countermeasure development and enable preparedness and response activities;
- Fostering the professional development of FDA scientists to ensure that FDA personnel maintain the skills and abilities to support the medical counter-measure mission; and
- Supporting regulatory science to create the tools, standards, and approaches necessary to develop and assess the safety, efficacy, quality, and performance of medical countermeasures.

FDA is also a critical partner in preparing for, and responding to, natural disasters, as demonstrated by its ongoing 2017 hurricane recovery efforts, including its work in Puerto Rico following Hurricane Maria. FDA performs extensive preliminary work in advance of storms to help prepare for potential impacts. For example, FDA utilizes storm prediction data and firm registration data bases to prepare maps to identify FDA regulated firms, including those that manufacture critical products that could be impacted by the storms. Where necessary, FDA may take contingency steps to help ensure a continuous supply of critical medical product manufacturing. The most significant role that FDA plays comes after the storm, as facilities come back on line and may need remediation, and farmers seek to put crops or farmland that were damaged back into commercial use. FDA has supported the many pharmaceutical and medical device manufacturers in Puerto Rico to help address and prioritize recovery operations based on the potential for medical product shortages based on public health needs. Many of the requests FDA received were for infrastructure support, primarily getting a reliable source of power, and FDA worked with partners at the Department of Homeland Security to support getting critical manufacturing back online. Through product registrations and communications with manufacturers, FDA was able to identify the medically necessary products manufactured in Puerto Rico and determine which were the top public health priorities. FDA continues to be focused on storm-related shortage issues, including shortages of saline solution and amino acids, as well as the cascading increase in demand for other medical products, such as empty IV containers which are now being used in higher quantities for compounded products. FDA has been in direct communication with manufacturers, distributors, hospitals and other health care providers, including the Department of Veterans Affairs (VA), and we are assessing existing product supply, demand trends and manufacturer capacity to increase availability of the empty IV containers.

Fostering Innovation in Medical Countermeasure Development

At FDA, we fully appreciate that the development of medical countermeasures can present complex and unique challenges. For example, it is not ethical to conduct human studies for many of the high-priority threat agents. In these situations, the Animal Rule, which enables animal efficacy studies to substitute for efficacy trials in humans if the results can reasonably be extrapolated to the expected human use, can be used to facilitate the development and availability of medical counter-measures. PAHPRA recognized the importance of the Animal Rule; and in 2015, FDA finalized guidance for product development under the Animal Rule, incorporating the learnings of considerable product development experience and providing scientific and regulatory expectations for animal data intended to support medical countermeasure approval.

To date, 12 medical countermeasures have been approved under the Animal Rule, including inhalational anthrax therapeutics, a botulism antitoxin, antibiotics for the treatment and prophylaxis of plague, and treatments for acute radiation syndrome. These approvals underscore the critical role the Animal Rule and animal studies can play in advancing medical countermeasures for some of the most challenging threats. Of note, through the use of regulatory science, FDA was able to approve the inhalational anthrax therapeutics and the

botulism antitoxin for use in children as well as adults, despite the fact that pediatric patients were not actually studied in clinical trials, due to ethical concerns.

However, for many threats there are not yet adequate regulatory science foundation, such as animal models to support medical countermeasure development or sufficient biomarkers to enable the extrapolation of data generated in animal models to humans. Without such tools, it is difficult to generate the data necessary to support regulatory decision-making.

FDA has established a broad and robust portfolio of cutting-edge research under MCMi's Regulatory Science Program to help develop these tools and promote innovation in the development of medical countermeasures. A few examples of projects include: supporting the development of organs-on-chips models to assess radiation damage in lung, gut, and bone marrow, and then using these models to test candidate medical countermeasures; collaborating to establish a publicly available genomic sequence reference data base for use by developers seeking to validate candidate multiplex in vitro diagnostic tests that could be used to diagnose multiple pathogens simultaneously; developing reference materials for developers to use to validate nucleic acid-based and serological diagnostic tests for Zika virus; supporting a project to identify and correlate biomarkers of host response to Ebola virus infection in animal models and humans to support medical countermeasure development; developing methods for obtaining safety and limited efficacy data from patients who receive medical countermeasures during public health emergencies; and establishing the Animal Model Qualification Program designed to support medical counter-measure development by promoting the development of animal models for use across multiple product applications, thereby minimizing duplication of effort and resources.

PAHPRA also provided authorities to ensure that FDA personnel are well-trained in how to review medical countermeasure applications for approval. Under these authorities, FDA has established a professional development program, including speakers' series and academic certifications, to ensure that FDA scientists are working through the regulatory challenges posed by new areas of science and technology as they relate to medical countermeasure development. FDA also has spent considerable energy and resources establishing an efficient approach to conduct and support training within the agency.

More recently, the Cures Act included several provisions that are intended to advance innovation in medical product development more generally, but will also help to facilitate the development of medical countermeasures, including the provisions to encourage novel trial designs, and to develop new antimicrobial drug products. Through the Cures Act, Congress also provided a new priority review voucher (PRV) program to help incentivize the development of material threat medical countermeasures. Under this program, FDA will award a PRV upon approval of a material threat medical countermeasure application provided that certain criteria are met. The PRV may in turn be used by the sponsor who receives it, or sold to another sponsor, who may then use it to obtain priority review for a product application that would otherwise not receive that benefit, enabling a developer to potentially bring a product to market sooner than otherwise possible—something that may be of great value to product developers. FDA plans to issue guidance to address medical countermeasure specific considerations with the intent to implement the program consistently with the other PRV programs, such as the Neglected Tropical Disease Voucher Program.

There are tremendous opportunities to continue to further the development of groundbreaking, innovative medical countermeasures, and the Agency intends to fully seize and build upon these opportunities. Toward that goal, this past July FDA announced the

launch of a comprehensive Innovation Initiative aimed at making sure its regulatory processes are modern and efficient so that safe and effective new technologies, including medical countermeasures, can reach patients in a timely fashion.

Facilitating Access to Safe and Effective Medical Countermeasures

Enabling access to medical countermeasures when they are needed is a high priority for FDA. Amended and new authorities provided by Congress have enabled the Agency to further prepare for, and better respond to, emerging public health threats. For example, PAHPRA amended FDA's EUA authority to provide additional flexibility for issuing EUAs. These additional flexibilities have enabled FDA to better support responses to emerging health threats by issuing nearly 40 EUAs to enable the emergency use of *In Vitro* diagnostic devices for H7N9 Influenza virus, Enterovirus D68 (EV-D68), Middle East Respiratory Syndrome Coronavirus (MERS-CoV), Ebola virus, and Zika virus. FDA also issued an EUA to enable the emergency use of an autoinjector medical countermeasure to maintain preparedness for chemical threats, which has been critical for supporting both warfighter and first responder preparedness goals related to an emergency involving nerve agents. The authority for prepositioning medical countermeasures provided in PAHPRA also proved useful to allow the manufacturer to ship, and the U.S. Government stakeholders to receive, certain strengths of the unapproved autoinjectors that were not yet authorized for use under that EUA.

PAHPRA also provided FDA with several new streamlined authorities to facilitate the emergency use of approved medical countermeasures without the need for issuing an EUA. For example, PAHPRA provided FDA with the authority to issue emergency dispensing orders (including mass dispensing at a point of dispensing (POD)) for approved medical countermeasures during an actual CBRN emergency without requiring an individual prescription for each recipient of the medical countermeasure, if permitted by state law or in accordance with an emergency dispensing order issued by FDA. FDA has used this authority to issue emergency dispensing orders to permit emergency dispensing of doxycycline and ciprofloxacin for post-exposure prophylaxis of inhalational anthrax, to ensure government stakeholders can rapidly provide these therapies in the event of an anthrax attack.¹

Another new FDA authority created by PAHPRA is the explicit ability to extend expiration dating of eligible FDA-approved medical countermeasures stockpiled for use in CBRN emergencies, if the extension is supported by an appropriate scientific evaluation. This authority streamlines FDA's ability to authorize expiration dating extensions without the need to issue an EUA, which will enable faster response, and has been crucial to FDA's ability to support preparedness efforts. For example, when production stopped after quality issues were identified in the manufacturing process of autoinjectors used for the treatment of nerve agent and insecticide poisoning, FDA used this authority to help prevent shortages of auto-injector products to help ensure that the Nation's warfighters and first responders continue to have ready access to these products. FDA also used this authority to extend the expiration date of

¹ The term "stakeholder(s)" means the public agency or its delegate that has legal responsibility and authority for responding to an incident, based on political or geographical boundary lines (e.g., city, county, tribal, state, or federal), or functional (e.g., law enforcement or public health range) or sphere of authority to prescribe, administer, deliver, distribute, or dispense oral doxycycline products in an emergency situation.

certain lots of doxycycline capsules held in strategic stockpiles by the Centers for Disease Control and Prevention, state and local public health, and other response stakeholders and issued draft guidance to provide recommendations to government stakeholders on testing that can be conducted to support future extensions, in order to help sustain preparedness levels.

The Cures Act also amended the EUA and related emergency use authorities to clarify their applicability to animal drugs. FDA encourages anyone interested in utilizing these authorities to contact FDA to discuss how to proceed.

Most recently, Congress passed H.R. 4374, legislation that amends FDA's EUA authority to enable FDA to issue EUAs for medical products to reduce deaths and mitigate injuries from agents that may cause imminently life-threatening and specific risks to United States military forces. Prior to the passage of this legislation, the EUA authority was only applicable to medical products to address CBRN threats. In addition, the legislation contains provisions codifying enhanced collaboration between FDA and DoD, in order to facilitate the development of medical products and countermeasures for the warfighter. FDA is working closely with DoD to implement these new and amended authorities as quickly as possible.

Conclusion

At FDA, we have made it a priority to proactively work with our private sector and government partners to help facilitate the translation of breakthrough discoveries in science and technology into innovative, safe, and effective medical countermeasures. FDA takes its responsibility seriously to help drive and foster innovation as part of advancing public health and our national security. Active FDA involvement is essential to encouraging industry engagement in medical countermeasure development. FDA remains deeply committed to working closely with its partners and continuing to use the authorities Congress provides to the fullest extent to help facilitate the development and availability of safe and effective medical countermeasures. We believe that partnership and innovation will continue to be key drivers to success in the medical countermeasure space and are taking steps to further empower FDA's scientific and clinical experts to drive the innovation necessary to help protect the Nation from the threats we may face.

FDA appreciates Congress's support in continually delineating, clarifying, expanding, and extending its authorities—and providing resources—to enable FDA to achieve its public health emergency preparedness and response mission. FDA stands ready to work with Congress and stakeholders to enable us to better achieve this critical work.

Thank you for inviting FDA to testify today. I am happy to answer any questions you may have.

Senator BURR. Thank you, Scott. Dr. REDD.

**STATEMENT OF STEPHEN C. REDD, M.D., RADM, DIRECTOR,
OFFICE OF PUBLIC HEALTH PREPAREDNESS AND RESPONSE,
CENTERS FOR DISEASE CONTROL AND PREVENTION, ATLANTA, GA**

Dr. REDD. Senator Burr, Chairman Alexander, and Ranking Member Murray.

I am Dr. Stephen Redd, the Director of the Office of Public Health Preparedness and Response at the Centers for Disease Control. And I am pleased to be here to talk with you today about the role the CDC plays in public health preparedness and response, including those responsibilities under the Pandemic and All-Hazards Preparedness Reauthorization Act.

The CDC is the common defense of the country against health threats. Our work to prepare and respond to health emergencies require that we build on our day to day in two particular areas.

No. 1, our longstanding partnership with state and local health departments and;

No. 2, our medical, scientific, and program expertise.

I will describe the three pillars of our defense strategy: science, surveillance, and service.

First, the CDC has a unique collection of scientific expertise that exists nowhere else in the world. We have the ability to identify agents causing illness, whether that illness is caused by an infectious microbe, or a chemical, or a radiation exposure.

We are ready to respond to a broad range of threats including diseases like Ebola, small pox, and H7N9 influenza.

The CDC plays a key role in discovering new and emerging infectious diseases using advanced detection techniques to identify pathogens quickly and more accurately.

Every year, laboratories from all over the world send hundreds of thousands of specimens to the CDC for testing.

The second pillar enabling the CDC's common defense of the country is surveillance. Public health surveillance is the collection, analysis, and use of data to target public health prevention and response. It is basically making sure the best information is used to make the right decisions.

Examples of this work include what we do to track influenza, the National Syndromic Surveillance system and the Global Disease Detection Program.

Influenza is probably the greatest natural health threat we face. Influenza viruses change continuously and require vigilance to detect these changes. The CDC provides support to every state, to several major cities, and to a number of ministries of health throughout the world to conduct influenza surveillance and laboratory work.

With the National Syndromic Surveillance Program, the CDC collects deidentified health information on causes of emergency room, urgent care, and hospital visits. We, along with state and local health departments, use the data in real time to detect abnormal situations requiring public health response.

The CDC's Global Disease Detection Operation Center monitors 30 to 40 outbreaks every day across the globe, 24/7, and assesses the potential risk to the United States from these events. In addition to science and surveillance services, the final pillar is supporting the CDC's common defense of the country.

Let me focus on three particular programs, the Public Health Emergency Preparedness Program, the Strategic National Stockpile, and the Cities Readiness Initiative.

In each of these programs, the keys to success are the close collaboration between CDC and state and local public health departments, and the connection of these programs to CDC's scientific expertise.

The Public Health Emergency Preparedness grants go to every state and support staff, enable exercises to test and validate capabilities, and pay for laboratory and communications equipment.

The Strategic National Stockpile is a \$7 billion repository of pharmaceuticals, medical supplies, and medical equipment that is available for rapid delivery to support responses to health emergencies.

The CDC's Cities Readiness Initiative enhances preparedness in the Nation's 72 largest cities where nearly 60 percent of the U.S. population resides. These funds are used to develop, test, and maintain plans to receive countermeasures from the CDC's Strategic National Stockpile and rapidly dispense them.

I would like to leave the Committee with three primary points about the CDC's role in public health emergency preparedness and response.

First, the CDC is the common defense of the country against health threats.

Two, CDC's preparedness work is built on a day to day foundation of our broad and deep scientific medical and program expertise.

Three, the CDC's longstanding partnerships with state and local health authorities are essential.

Thank you for the opportunity to testify today. [The prepared statement of Dr. Redd follows:]

PREPARED STATEMENT OF STEPHEN C. REDD

Chairman Alexander, Senator Murray, and other Members of the Committee. I am Rear Admiral Stephen Redd, Director of the Office of Public Health Preparedness and Response at the Centers for Disease Control and Prevention (CDC). I appreciate the opportunity to be here today to discuss CDC's public health preparedness and response mission, and the agency's role in implementing the Pandemic and All-Hazards Preparedness Reauthorization Act of 2013 (PAHPRA).

CDC provides for the common defense of the country against public health threats. Through our dedication to science, surveillance, and service, CDC focuses on protecting the public health of the Nation from threats such as emerging infectious diseases, natural disasters, and terrorism.

In carrying out the mission set forth under the Pandemic and All Hazards Preparedness Reauthorization Act, CDC draws on expertise from throughout the agency. CDC's expertise includes world-class laboratory testing, surveillance (for disease detection), epidemiology, guidance to healthcare providers, incident management, logistics, emergency risk communication, disease control programs, distribution of medical countermeasures, human and animal medicine, and responder health and well-being. Our multidisciplinary workforce enables an integrated national system that is nimble and prepared to detect and respond to any developing situation that could affect the health of people in the United States. In addition, CDC draws on its long-standing relationships and close collaboration with state and local

partners to protect the health of communities across the country, and collaborates closely with the Assistant Secretary for Preparedness and Response (ASPR), the Food and Drug Administration (FDA) and other Federal partners.

CDC experts lead and staff every activation of the agency's Emergency Operations Center (EOC), ensuring response activities are effective and efficient. HHS/CDC has an emergency management program accredited by the Emergency Management Accreditation Program. CDC activated its incident management system for 67 responses over the last 16 years, between September 2001 and December 2017. During a response, CDC's EOC rapidly deploys scientific experts, coordinates the delivery of supplies and equipment to the incident site, monitors response activities, provides resources to state and local public health departments, and disseminates timely and accurate information within government, to health care providers, and to the public. During the agency's Zika and Ebola responses, CDC deployed over 1,700 and 3,700 staff, respectively. CDC also responds to public health events that do not require EOC support. In fiscal year 2017, CDC assisted state, local, and overseas public health authorities in 23 epidemiologic investigations of emerging infectious disease outbreaks as well as more than 20 environmental responses.

CDC Programs under the Pandemic and All Hazards Preparedness Reauthorization Act

The Pandemic and All Hazards Preparedness Reauthorization Act of 2013 (PAHPRA) reauthorized several public health preparedness programs. The discussion immediately below focuses on two of those programs: CDC's Public Health Emergency Preparedness cooperative agreement program (which includes the Cities Readiness Initiative (CRI)) and the Strategic National Stockpile (SNS). Later in the testimony I will discuss CDC's work related to a third PAHPRA program, bio-surveillance.

Public Health Emergency Preparedness Cooperative Agreement (PHEP) Program: The PHEP cooperative agreement program is the largest CDC state program and provided approximately \$600 million to state, local, and territorial public health departments in 2017. The program developed the first playbooks for public health preparedness and response, and has been instrumental in integrating state and local health departments into their jurisdictions' emergency response structures. PHEP currently supports 62 awardees—including all 50 states, eight territories and freely associated states, and directly funded cities (New York City; Washington, DC.; Chicago; and Los Angeles). Funding is awarded according to a base plus population formula prescribed by statute, which ensures a minimum amount of funding to each awardee. These funds support preparedness and response staff, enable exercises to test and validate capabilities, provide for timely training, and pay for laboratory and communications equipment essential to maintaining preparedness. In addition, CDC personnel support PHEP awardees by helping to identify and address gaps in preparedness capabilities, providing planning resources to ensure the needs of at risk individuals are incorporated into response strategies, and improving response capabilities from experience gleaned during public health responses, most recently to Ebola and Zika.

Strategic National Stockpile (SNS): The SNS is the largest federally owned repository of vaccines, drugs, medical supplies, Federal Medical Stations, and medical equipment available

for rapid delivery to support federal, state, and local response to health security threats. The SNS was created in 1999 to ensure the Nation's readiness against public health emergencies by ensuring delivery of lifesaving medical countermeasures (MCMs) during deliberate or naturally occurring outbreaks and other events that threaten public health. Since its inception, SNS products and staff have been deployed more than 100 times for events ranging from natural disasters to infectious disease outbreaks. CDC works with the HHS Assistant Secretary for Preparedness and Response and with other Federal agencies through the Public Health Emergency Medical Countermeasures Enterprise (PHEMCE) to prioritize Federal investments in medical countermeasures based on analysis of risk, benefits to the American people and sustainability of the MCM pipeline.

Management of the SNS and deployment of its assets are complex endeavors which rely on a broad range of scientific expertise, surveillance systems, public health communications systems, and state and local partners. The SNS ensures that the right medical countermeasures and supplies are available when, where, and in the quantity needed to stop or slow a public health emergency and save lives. And, scientific experts ensure that medicine and supplies expeditiously get to our public health partners at the state and local levels, who have had the necessary training, exercises, and clinical guidance to effectively and efficiently receive those assets from the SNS and get them to those who need them.

Cities Readiness Initiative (CRI): CRI, funded through the PHEP cooperative agreement, enhances preparedness in the Nation's largest population centers, where nearly 60 percent of the population resides. The 72 cities (at least one in every state) use CRI funds to develop, test, and maintain plans to quickly receive medical countermeasures from the SNS and distribute them to local communities. This program, through reliance on local boots on the ground, enables effective response to large-scale public health emergencies needing life-saving medications and medical supplies.

Public Health Preparedness through Science, Surveillance and Service

In carrying out its public health mission CDC's subject matter experts from across the agency collaborate to detect and respond to emerging threats that could affect Americans' health.

Science

Exceptional and world-renowned scientific expertise and world-class laboratories ensure CDC is ready and able to respond to a broad range of threats, including highly hazardous and infectious diseases like Ebola, smallpox, and H7N9 influenza. For example, CDC's research on the smallpox virus helps find better drugs to treat the disease, stop the virus from spreading, make safer vaccines, and improve tests to detect the virus. Additionally, CDC's global influenza capacity-building efforts helped facilitate the rapid detection of the novel Asian lineage influenza A (H7N9) virus in 2013. Most human infections resulted from exposure to infected poultry, but CDC assesses that the virus poses the greatest pandemic risk of all influenza viruses not yet circulating among humans, and is working with global health partners to monitor that virus and detect changes in it that could trigger a pandemic. CDC has developed two candidate vaccine viruses and shared them with vaccine manufacturers, for use

in BARDA-supported vaccine production and in clinical trials by NIH's National Institute of Allergy and Infectious Disease. If the H7N9 virus develops the capacity to spread among humans, an effective vaccine would be key for preventing a pandemic.

CDC plays a critical role in discovering new and emerging infectious diseases, using advanced molecular detection techniques that combine next-generation genomic sequencing, high-performance computing, and epidemiology to identify pathogens faster and more accurately. Laboratories from all over the world send specimens to CDC, often in cases where the cause of illness is unknown. Annually, CDC receives hundreds of thousands of specimens to examine and helps diagnose hundreds of cases of unexplained illness or death. Through advanced molecular detection investments, CDC is seeing improvements in faster detection of outbreaks (catching them when they are smaller) and in faster development of diagnostics, applying these technologies in dozens of areas such as foodborne disease, influenza, antimicrobial resistance, hepatitis, pneumonia, and meningitis. CDC shares genetic sequencing technologies with state and local health departments, and funds them to acquire new technology that helps them to respond quicker and more efficiently at a local level.

CDC is critical to preparing for the next influenza pandemic. In an influenza emergency, CDC's public health and infectious disease experts use advanced molecular detection techniques to identify disease strains that could cause a pandemic, release recommendations for the prevention, diagnosis, and treatment of disease, and provide communication to the Nation about the pandemic. For example, each human case of infection with a new animal influenza virus represents the potential for a pandemic. CDC receives and studies viruses like these in its laboratories to better understand where and how they spread and the nature of illness they cause. This informs development of clinical and public health recommendations before and during emergency responses. In the event of an influenza pandemic, CDC's scientific experts use the best epidemiologic and laboratory data available to update or develop guidance to inform purchasing, distribution, and use of medical counter-measures including vaccines, antiviral drugs, respirators or masks, and ventilators. CDC also develops and evaluates solutions to lessen the impact of an influenza pandemic through non-pharmaceutical interventions or actions that people and communities can implement to help slow the spread of influenza, such as staying home when ill, coordinating school closures, and postponing mass gatherings.

CDC has longstanding collaboration with countries and institutions around the world. These strategic partnerships coupled with forward deployment of our scientists stationed in more than 60 countries enable CDC to identify new pathogens, assess risks, and devise effective control measures. Our partnerships provide the platforms for timely sharing of laboratory specimens, innovations and distribution of diagnostic materials and technologies to prevent epidemics, and promptly respond to disease outbreaks before they cross international borders.

Vector-borne diseases present another preparedness challenge, as we saw in the Zika emergency. CDC is one of the Nation's public health authorities on vector-borne diseases, like Zika, plague, and dengue. CDC scientists who specialize in vector-borne disease have deep expertise in entomology, microbiology, virology, veterinary medicine, zoology, and public health that does not exist elsewhere. These experts develop diagnostic tools and clinical guidance, as well as methods of treatment, prevention, and vector control, in order to slow the spread of these diseases. For example, CDC scientists have determined that a natural plant ingredient called nootkatone effectively repels and kills the mosquitoes and ticks that

can spread disease. Nootkatone appears to work differently than available insecticides, and it could help fight mosquitoes that are resistant to existing insecticides.

CDC's scientific experts protect people from environmental health threats like contaminated water, radiation, and chemical emergencies. To do so, CDC identifies the environmental exposures that make people sick, investigates how those exposures are transmitted in the environment, and finds ways to eliminate the threat to people's health. For example, CDC's radiation guidelines help public health officials and clinicians prepare for, and respond to, radiation emergencies and treat exposures.

The list of CDC's scientific expertise is much longer than I have detailed, including myriad chronic diseases and also includes foundational scientific expertise critical to effective public health impact such as in the areas of workforce, laboratory systems, and data sciences.

Surveillance

Public health surveillance—the collection, analysis, and use of data to target public health prevention and intervention activities—is the foundation of public health practice. CDC monitors health surveillance information around the clock to detect and track diseases and protect Americans. As one example, following 9/11, CDC made investments in enhancing syndromic surveillance—using health-related data based on patient symptoms that precede diagnosis—as an early warning system for bioterrorism. This system now allows officials to detect a much wider range of health threats—from opioid overdoses to chemical spills to disease outbreaks. Moreover, CDC collects, analyzes, and interprets human, animal, environmental, and food surveillance data, in order to identify and respond to potential health threats before they become emergencies. In aggregate, CDC's specialized surveillance systems provide prompt situational awareness and early warning for unknown or unexpected threats. CDC's surveillance activities directly support states in their primary responsibilities in protecting the public's health. Surveillance data, collected in collaboration with domestic and international partners, inform CDC's threat assessments and ensures response actions are at the right speed, scope, and scale to protect Americans.

CDC supports integrated disease surveillance activities at the state and local level through funding and provision of surveillance tools and services. The following are examples of the surveillance systems and support that CDC provides to state, local, and territorial public health departments to develop and strengthen their surveillance activities:

- *National Notifiable Diseases Surveillance System (NNDSS)*: NNDSS is a nationwide system that enables all levels of public health—local, state, territorial, Federal, and international—to collect and share data on approximately 100 diseases and conditions that are required to be reported in all 50 states, and keeps them under continuous surveillance. This system provides comprehensive, timely, and high-quality data for public health decision-making, enabling CDC programs to work with state partners to better monitor disease occurrence, identify potential outbreaks, recognize emerging trends, track the impact of public health interventions, and respond..
- *Influenza Surveillance*: Influenza viruses are constantly changing, and, thus, require continued vigilance to protect the United States and the rest of the world from both seasonal and pandemic influenza threats. Influenza surveillance, both epidemiologic

and virologic, is at the core of influenza preparedness. The surveillance platforms used year round to combat seasonal influenza threats serve as the foundation for pandemic influenza surveillance. CDC provides support to every state, and several major municipalities and territories, to conduct influenza surveillance and laboratory work. For many decades, CDC has served as an international leader in global influenza surveillance. We have partnered with more than fifty countries to establish, maintain, and expand influenza surveillance and laboratory capacity, in order to find influenza viruses where they emerge as quickly as possible to mitigate their potentially devastating impact on the United States. Domestic funding supports seasonal influenza surveillance through a network of interrelated systems that provide data on where influenza and influenza-like illnesses, hospitalizations, and deaths occur.

- *National Syndromic Surveillance Program (NSSP)*: CDC, through state and local collaborations, collects deidentified health information on emergency room, urgent care, and hospital visits, as well as pharmacy and laboratory data. This investment has revolutionized public health surveillance to include this new type of data collection on top of traditional type and methods of data collection. States and local public health departments use the syndromic data to detect and characterize abnormal situations meriting further public health investigation. This strengthens local public health capacity to detect, respond to, and manage, outbreaks and other critical public health events. CDC has negotiated access to the data to enable situational awareness at regional and national levels. The series of three recent hurricanes presents a poignant example that demonstrates the usefulness and flexibility of this asset. Before the hurricanes, CDC and ASPR had begun establishing a mechanism to share National Disaster Medical Assistance Team (DMAT) data during mass gatherings. As the hurricanes hit, CDC and ASPR established data flow mechanisms and rules, and in 2 days put in place a system to receive hourly data from DMATs, resulting in timely information that helped responders target communities at greatest need for public health interventions.
- *Vector-Borne Surveillance*: CDC operates systems that allow for national and state-based monitoring of specific vectors, such as ticks and mosquitoes, which carry diseases and pose risks for outbreaks. These systems monitor laboratory documented cases of disease, allowing for the early detection of outbreaks and helping decisionmakers determine when and how to act in the interest of the public's health. State, territorial, city, and local health departments populate CDC's surveillance systems to inform vector control and management activities.
- *Antibiotic Resistance Surveillance*: Beginning in fiscal year 2016, Congress recognized the large and growing threat of antibiotic resistance and appropriated funding to CDC to detect and respond to resistant pathogens, prevent the spread of resistant infections, and collaborate with partners to encourage innovation for new prevention strategies. CDC has multiple surveillance systems that can detect and track resistant threats across healthcare, food, and the community. One important investment begun in 2016 is CDC's Antibiotic Resistance Laboratory Network (ARLN), which supports nationwide laboratory capacity to rapidly detect antibiotic resistance in healthcare, food, and the community, and inform local responses to

prevent spread and protect people. The ARLN includes seven regional laboratories, the National Tuberculosis Molecular Surveillance Center, and laboratories in 50 states, five cities, and Puerto Rico. The ARLN is vital to detecting new and emerging resistant pathogens, including those that are untreatable, to trigger infection control response measures to prevent spread. The ARLN collects actionable data on threats including the “nightmare bacteria,” carbapenem-resistant Enterobacteriaceae (CRE), *Candida auris*, and *Neisseria gonorrhoeae*; some strains of these pathogens have become resistant to all or nearly all available antibiotics. In addition, samples from the ARLN can be made available to researchers to support innovations in antibiotic and diagnostic development.

- *Global Disease Detection*: CDC’s Global Disease Detection (GDD) Operations Center monitors outbreaks 24/7 across the globe, assesses their potential risk to the United States and communities around the world, and improves global public health surveillance. The GDD Operations Center monitors approximately 30–40 public health threats each day, including outbreaks, disasters, poisonings, and chemical, radiological, or nuclear events. Since 2007, CDC has tracked more than 170 unique diseases globally and identified outbreaks in more than 190 countries. This tracking provides the agency with critical early warning and response capabilities.
- *Global Polio Surveillance*: CDC, as part of the Global Polio Eradication Initiative, supports polio surveillance to track potential cases and circulating viruses and to effectively target polio immunization efforts. The goal of these efforts is polio elimination in every country and eventual worldwide eradication, and we are closer than we have ever been to achieving that monumental accomplishment. In 2017, the Global Polio Eradication Initiative identified just 20 wild poliovirus cases worldwide, down from 350,000 cases in 1988 when the global eradication initiative began. The global polio surveillance system, coupled with the CDC-supported Global Poliovirus Laboratory Network (comprised of 145 laboratories around the world), also detects and assists in the diagnosis of other epidemic prone diseases such as measles, rubella, and yellow fever.

Taken together, these surveillance systems provide an early warning alert, allowing CDC to protect the health of Americans through rapid, evidence-based action.

Providing Public Health Services

State and local public health agencies are the cornerstones of preparedness and response. When states are prepared to respond, communities are better protected and more resilient in the face of threats. CDC has long-established relationships with state and local officials, and coordinates with them effectively and efficiently during public health emergency responses. CDC also collaborates with foreign ministries of health to protect global health security that directly impacts United States health security. Examples of CDC’s critical support of state, local, and foreign health agencies to ensure they are ready to respond to emergencies include:

- 24/7 public health consultation and disease expertise.

- Enabling a quality public health laboratory system while maintaining critical laboratory infrastructure and specimen testing support.
- Managing and delivering medical countermeasures.
- Public health workforce development that complements preparedness-specific provision of guidance, training, and exercises to ensure jurisdictions are ready to detect and respond to an emergency.

In the event of an outbreak, bioterrorist attack, or chemical or radiological release, laboratory capacity is essential to quickly detect, diagnose, and treat those who are impacted. CDC's Laboratory Response Network (LRN) maintains an integrated network of state and local public health, Federal, and international laboratories that can respond to all types of public health threats. The linking of state and local public health laboratories, and veterinary, agriculture, and water-and food-testing laboratories is unprecedented and provides for training, rapid testing, timely notification, and secure messaging of laboratory results. With the LRN, CDC has developed and deployed tests to combat our country's most pressing infectious and non-infectious health issues, from Ebola to Zika to ricin toxin to nerve agents. CDC ensures the Nation is able to respond to influenza pandemics, vector-borne or vaccine-preventable disease outbreaks, other emerging infectious disease threats, and environmental health threats by supporting planning efforts among health departments, hospitals, and emergency responders. CDC tests its pandemic influenza response capabilities with federal, state, and local partners through virtual tabletop and functional exercises. CDC evaluates and improves its response plans based on lessons learned from previous responses and exercises. CDC supports state and local health departments directly during vector-borne and environmental health incidents by developing and evaluating novel repellents and other prevention tools; improving and deploying diagnostic tools and tests; responding to toxic health threats; and providing unique expertise and training regarding radiation.

The existing public health system, its people, networks and resources, form the basis for response to health emergencies. For example, CDC's National Center for Immunization and Respiratory Diseases funds state infrastructure awards, manages vaccine shortages, prevents disease outbreaks and responds early and rapidly should they occur, and stands ready to respond quickly and comprehensively to other urgent emergencies requiring vaccination such as a pandemic or biologic attack. CDC also funds state and local public health agencies through the Epidemiology and Laboratory Capacity for Infectious Diseases cooperative agreement (ELC). This funding allows jurisdictions to strengthen their basic epidemiologic and laboratory capacity to address infectious disease threats. Multiple CDC programs use the ELC platform to protect the public health and safety of the American people by supporting health departments to effectively detect, respond to, prevent, and control a wide range of known and emerging (or reemerging) infectious diseases. These CDC programs and others provide ongoing support to prevent, prepare for, and respond to public health emergencies.

An outbreak that starts in another country can hit our shores in a matter of hours. Strengthening global health security protects Americans' health. New diseases, like MERS and influenza H7N9, can emerge without warning and have the potential to cause widespread infection and fear. CDC works with 31 Global Health Security Agenda partner countries to help them build the core public health capacities necessary for identifying and containing outbreaks before they become epidemics that could affect us all. This work is focused on

strengthening four critical areas: surveillance, laboratory, workforce development, and rapid response capability. In addition, CDC medical and public health officers staff United States Quarantine Stations that are located at 20 ports of entry and landborder crossings where the majority of international travelers arrive. These health officers are the first line of defense to prevent the introduction and spread of infectious diseases.

Conclusion

I want to leave the Committee with three primary points about CDC's role in public health emergency preparedness and response.

- CDC is the common defense of the country against threats to public health,
- CDC's preparedness work is built on a foundation of our broad and deep scientific, medical, and programmatic expertise, and
- CDC's longstanding partnerships with state and local public health authorities are essential to the health security of our country.

Through the three interconnected pillars of science, surveillance, and service, CDC plays a critical role in working to ensure that the United States is ready to respond to public health emergencies. CDC has over 70 years of experience in bringing top scientific expertise to health emergencies and remains a trusted partner in the United States and around the world. CDC stands ready to do its part to protect the health and well-being of the American public and save lives. We cannot necessarily predict the next disaster, but we know that being prepared protects health, saves lives, and prevents economic losses.

Thank you for the opportunity to testify.

Senator BURR. D. Redd, thank you very much.

You won the award for getting the closest to the 5 minutes of all our witnesses today.

[Laughter.]

Senator BURR. The Chair would recognize himself and the Ranking Member, and then Senator Alexander, Senator Casey, and then Members in the order of attendance to today's hearing.

Dr. Bob, my first question is simple. Are we prepared for public health threats we face?

Dr. KADLEC. Sir, I would have to say equivocally for some, but not all.

I think the reality is when this concept of PAHPA first came up in 2005, we had witnessed the terrorist attacks of 9/11. We were anticipating potentially a pandemic and we had just experienced Katrina. But those are all in the rearview mirror in terms of the threats that we are prepared to deal with.

Quite frankly, if you had to look at Nation State threats that we are considering today, or multiple Nation States that are willing to use terrible weapons against, both physical as well as potentially cyber, I think we are not prepared. And quite frankly, those are the things that keep me up at night as well as a pandemic that could emerge again from Asia. As well as the risks that have come up that Dr. Gottlieb identified with synthetic biology tools now that allow nefarious people to do unimaginable things potentially.

So I think we have a long way to go. We have done very well in some areas; again, a compliment to the effort that was done by the Federal Government in support of state and local authorities. And again, for those three hurricanes nearly consecutively, I think that was a great commitment of effort by everyone.

But there is no time to rest on our laurels in that respect.

Senator BURR. The statute is very clear on BARDA's specific and targeted medical countermeasure mission to ensure that BARDA is staying focused in bringing forward the countermeasures we need to protect the American people from a range of chemical, biologic, radiologic, and nuclear threats. All of BARDA's work should be tied to this threat context.

Why is it important that BARDA's mission not be diluted by matters or mandates that would require BARDA work on areas outside of those tied to threats specifically? And how does the comment of 34 innovations out of BARDA relate to a focus on its mission?

Dr. KADLEC. Yes, sir.

Well, I think the key thing here is to remember what the mission was originally. And again, BARDA was only part of the puzzle here.

Project BioShield, which was a 10-year advanced appropriation, was another critical element of that formula of success, which was a guaranteed market to manufacturers should they get across the finish line.

But the key issue that you have raised, sir, is that we cannot boil the ocean. Quite frankly, the BARDA model works. The resources that have been given to BARDA to date have been somewhat limited. We have had, literally in some circumstances, to rob Peter to pay Paul given events that have transpired with Ebola and other events.

We do not have a sustained level of funding necessarily, a line item for pandemic influenza, for example. That would give us great confidence that we would have a sustained, uninterrupted funding stream.

So the answer is arguably, you could do more things, but the answer is you cannot do more things with limited resources. If we focus on the national security mission which, I think, is vital—again, vital to the role of BARDA—then I think we have to stick to our lane and highlight the fact that right now, to use a defense analogy, we are operating with about half an aircraft carrier of resources to basically do this mission. A national security mission to basically protect 320 million people and that is a challenge.

Senator BURR. Dr. Gottlieb, in your experience, what is working well in the agency's review of medical countermeasures? And what challenges have you seen in the medical countermeasure pipeline?

Dr. GOTTLIEB. I think we are doing a much better job now. I look at this over a 15 year period.

I came into the agency shortly after the animal rule was implemented back in 2002. Between my two tours at the agency, I think we are doing a much better job at leaning in with respect to trying to bring some of these technologies forward; trying to look at ways that we can lean forward and develop the animal models that are going to form the basis of some of the product approvals; trying to put out perspective guidance and talk to manufactures and provide more regulatory clarity.

I think there are still challenges around the incentives in this market. Frankly, I think having been on the other side of this in the private sector, the prospect of being able to commercialize something just for stockpiling purposes sometimes is not enough of an incentive to offset the enormous capital costs of some of these endeavors.

I think we are also looking at, we focused on some of the immediate dangers, some of the pathogens we knew and we are developing countermeasures on them. I think we are looking at a future where it is going to be much easier to bioengineer some of these things in ways that we cannot fully anticipate and create very new risks.

Senator BURR. Senator Murray.

Senator MURRAY. Well, thank you very much to all of you.

In the wake of Hurricane Irma, as hospitals were evacuating, the top priority was protecting vulnerable populations including people and individuals with disabilities, and children, and pregnant women.

In every public health emergency, we have to pay unique attention to people with functional needs that put them particularly at risk. That is true for preparedness planning and for emergency response, including, for example, making sure that there is adequate medical countermeasure development and dosing guidance for children and pregnant women.

PAHPA actually acknowledges that there must be specific attention paid to at risk individuals, and we want to build on that last authorization, because I think we can do better.

So I wanted to ask each of you to briefly describe your agency's efforts to meet the needs of all people. And, what more can we do to ensure that when it comes to public health preparedness, we are prepared for everyone?

Dr. Redd, let me just start with you, and if we could, just go down the panel.

Dr. REDD. Thank you for that question.

Let me just highlight a couple of things that we are doing at the CDC.

First of all, our guidance through the Public Health Emergency Preparedness Program requires that states have a plan for persons with functional needs. So that is part of the planning process.

We also work closely with the American Academy of Pediatrics and the American College of Obstetrics and Gynecology, depending on what the emergency is, but work with them to make sure that those needs are being covered.

I would also say in the stockpile that we have made progress in procuring products that are needed to treat children.

For example, there are 100,000 treatment courses of Oseltamivir in suspension form that are intended, or targeted, for children.

Senator MURRAY. What could we do better?

Dr. REDD. I think there is always more work to do.

I think that we need to make sure that these plans are exercised and that we have actually covered all the bases. That they are not just written on paper, but that we actually are able to execute the plans that we have made.

Senator MURRAY. Dr. Gottlieb.

Dr. GOTTLIEB. I would just highlight that PAHPA gave us new authority to put forward, to your point, treatment guidelines that can help guide the applications of some of these therapeutics, particularly with respect to pediatric dosing, which we have used. We have approved 12 drugs under the animal rule; 7 have been approved with pediatric dosing requirements.

I think this is something that we can continue to do better. I think one of the ways that we are going to do that is to have better development of animal models that have better natural histories associated with the pathogens in those animal models that allow us to predict what the therapeutic impact is going to be on a pediatric population.

So, this is some basic research that we need to do to develop those models that are going to, then, allow us to extrapolate into a pediatric population; and other populations, for that matter, other vulnerable populations, to your point, and allow us to have dosing guidelines for those populations.

Senator MURRAY. Is there anything we can do within PAHPA to help improve that?

Dr. GOTTLIEB. I think to Senator Burr's point as well, I think this, as a scientific basis, still needs further development. PAHPA gave the agency resources and we have developed discrete expertise in this area as a result of the legislation.

I think that is a place where we can continue to make more investment.

Senator MURRAY. Okay. Dr. Kadlec.

Dr. KADLEC. Thank you, ma'am, for the question.

I would just like to highlight during the hurricanes, we actually did some very specific things around people with functional disabilities.

I do not know if any of the Members have heard of emPOWER. It is a program that allows us to basically identify, in the CMS data base for Medicare, people who are dependent on durable medical equipment.

Based on requests from states, we can provide actually very specific information where these people live by ZIP Code and by address. In cases like Irma, Florida was able to do a reverse 9-1-1 call to those people at risk well before any evacuation orders went out to the general public to advise them that they should consider leaving before things got worse.

In the cases of Maria, we actually used that data to identify, on the islands St. Thomas and St. Croix, people who were dialysis dependent. And after the storm passed, we were able to basically link up with the urban search and rescue teams, and actually recover dialysis dependent people, and basically evacuate them to safety. So there is that part of it.

One of the limitations currently is that it is only for Medicare data. The State Medicaid data is limited. We can do that if we have access to that and provide the same information. So that is one area that we could probably benefit from working with you all to see how we can have the states work collaboratively to use that information prospectively.

To add to the points that were made by the other gentlemen, clearly BARDA has looked at specific products for pediatric patients, as well as people with immune-compromise, and there are products that are in the stockpile today that are to benefit both of those populations.

One of the areas, and I highlighted it in my testimony, is on the National Disaster healthcare System. One of the specific areas we would like to do is take the learnings or lessons learned from Ebola where we created a national Center of Excellence at Nebraska University for infectious disease and replicate that for other very important trauma-related or disaster-related areas like pediatrics.

We think that that would be a way where not only can you create the necessary, if you will, critical mass of expertise, but also teach through telemedicine and through teleconsultations to provide support during disasters.

The last area I would like to do, and a shout out to our V.A. colleagues, is the V.A. was a very significant contributor to our response to Harvey. HHS responded and took care of 36,000 patients. The V.A. provided care to 21,000 patients, many of those were V.A. beneficiaries, but some of those, many of those were families of V.A. beneficiaries. And then a larger number were actually the general public.

The V.A. has unique capabilities as it relates to geriatric populations, and that is one area that we can probably benefit from in terms of utilizing some of their expertise.

Senator MURRAY. Thank you very much. Senator BURR. Chairman Alexander.

The CHAIRMAN. Thanks, Mr. Chairman.

Dr. Kadlec, Dr. Gottlieb, let us talk about the flu. This is the 100th anniversary of the 1918 influenza pandemic that killed an estimated 50 million people worldwide; 600,000 in the United States.

According to the Centers for Disease Control, year in and year out, between 12,000 and 56,000 Americans die as a result of seasonal flu.

We heard last week in our opioids hearing that opioids kill more Americans than car accidents. And those statistics that I just read would suggest that in a severe year, so could the flu.

Dr. Collins, the head of the National Institutes of Health, has made the prediction before our Committee that if we keep up our investments in biomedical research—which Senator Blunt, and Senator Murray, and the rest of us have been doing pretty well the last 3 years—that we may have a universal flu vaccine, as well as a vaccine for Zika, within the next decade.

Dr. Fauci at NIH has said that the most effective method for protecting Americans against another pandemic influenza is to encourage and invest in the development and stockpiling of influenza vaccines that will broadly protect against the virus.

Well, in Tennessee right now, the hospitals are filling up with people with the flu. So Dr. Kadlec and Dr. Gottlieb, if researchers at NIH, or any partners with them, discover a platform technology that could speed the development of a universal flu vaccine, what would BARDA do to support the advanced research and development of that technology?

Dr. Gottlieb, what is the FDA ready to do to encourage the use of that technology for new and innovative vaccines?

I have 3 minutes.

Dr. KADLEC. Chairman, I will be very brief, then, in the sense that BARDA has an integrated portfolio with NIAID. So once a product gets through Phase 2a clinical trials, it would be transitioned over to BARDA, which would take the advanced development through to fruition. So that part of it is done.

They have the capacity to basically identify manufacturers who could produce that either in eggs, or tissue cell culture, or emerging technologies.

The CHAIRMAN. Dr. Gottlieb.

Dr. GOTTLIEB. Yes. I will just quickly add, we already have, in development, vaccines that might be universal flu vaccines that, presumably, could elicit a T-cell response and could achieve what you are outlining.

We continue to provide advice to clinical developers and manufacturers on the proper pathway for looking at trying to bring those new technologies through.

I would point to one place where the legislative suite that we have adopted to try to address some of these biological threats has been helpful in the development of manufacturing capacity. That could greatly aid in the scope of these new vaccines, particularly cell-based manufacturing, which we have made a lot of investments in, as you know, that could provide the proper platform for the development of these vaccines.

The CHAIRMAN. Dr. Gottlieb, this is a related matter.

We are all concerned about Puerto Rico and the impact of the hurricane there. I think you told me at one point that maybe one-third of the economy of Puerto Rico has to do with medical technology.

Is that right?

Dr. GOTTLIEB. That is about right. It is about 30 percent.

The CHAIRMAN. And many of those facilities, as you described, were destroyed.

Are they rebuilding in Puerto Rico, or are they rebuilding other places, or do you know yet, because that could have a major effect on Puerto Rico's future?

Dr. GOTTLIEB. Right. And we are obviously very concerned about the situation in Puerto Rico for a host of reasons, not the least of which is that the Puerto Rican economy is very dependent upon that skilled manufacturing base.

I am happy to tell you that all of the facilities that we are concerned about—that produce product that we were worried could go into shortages if the facilities continued to remain offline—are now back on the grid.

So the facilities themselves actually did not sustain a lot of damage. It was the power grid and the infrastructure in between the facilities to try to move equipment in and off the island, and that sustained a lot of the damage. The facilities actually were fairly hardened.

But the ones we were worried about are back on the grid. There are still some facilities that are not on the grid, but they have such redundant electric generation capacity that we do not really have concerns about the product supply coming out of facilities.

So the situation now looks a lot better than it did 4 months ago. The CHAIRMAN. Mr. Chairman, I think my time is about up, and

I will give the rest of it back. Senator BURR. Senator Casey.

Senator CASEY. Thank you, Mr. Chairman.

I wanted to start with the reference that I made earlier to the train derailment in Philadelphia as an example of good preparation. Part of that has its origin in the fact that it happened in an urban area where you have not just the resources, but you have hospitals and the healthcare infrastructure, which is close by way of distance, as well as by way of coordination.

I represent a state that has 48 rural counties out of a total of 67 counties. So we have a lot of small towns and rural areas where you do not have the institutional capacity necessarily. In the event of an emergency, that could be exacerbated by distance and other challenges, so you have this type of gap or potential gap, where some communities may be particularly vulnerable.

I would start with Dr. Kadlec and then go to Dr. Redd.

In terms of the Hospital Preparedness Program, the so called HPP, as well as PHEP, how do those programs attempt to close the gap in preparedness among states and regions?

Dr. KADLEC. Thank you, sir, for the question.

I think the point is that the way we are structuring it right now, we are trying to actually build healthcare or promote healthcare coalitions which are collections of hospitals, as well as other entities like emergency medical services. So you can build a regional.

That is why we would like to expand that effort to basically do it so not only would it cover specific regions within a state, but statewide and across states so that you can develop a much stronger backbone, if you will, to do this.

I think the idea of basically building out the National Academy of Sciences' study on trauma systems is worthy of reviewing because it highlights the important role that has a foundational capability for the country. Not only for day to day routine activities, but for these extraordinary events, train derailments that happen not only in Pennsylvania, but in the State of Washington, as an example, become a central piece of that.

My interest in this is seeing how we can leverage all those pieces together with some of the Federal assets the V.A. identified. Madigan Army Medical Center was a critical first responder in the train derailment in Washington State.

The thing is, how do we basically build, forge a public-private partnership for those purposes that can basically strengthen it? So not only do you have the transport mechanisms with emergency medical services, but also telemedicine and teleconsultation that would be available from this specialty services, these Level I trauma service hospitals or Level I expert hospitals like Nebraska to basically deal with a range of topical areas.

Senator CASEY. Doctor, before moving to Dr. Redd, I just want to inject another question.

This is an authorizing Committee and a reauthorization process. But I want to specifically ask, in light of the question I posed, are there additional authorities you need or additional dollars?

Dr. KADLEC. Sir, I would suggest both. We have a \$3.3 trillion healthcare system for which, right now, we invest approximately \$250 million annually for preparedness and resilience. I think it just highlights the fact that it is kind of a drop in the bucket.

I do not think it is necessarily the role of the Federal Government to pay for the whole bill, but certainly, we need to look at a variety of incentives, whether that is through CMS reimbursements, whether that is through insurance programs, or tax benefits that would incentivize hospitals to do it.

Our conversations with some of the outside partners, we held kind of a listening session with 35 stakeholders last week, including hospital associations. They are all willing and we have the hospitals volunteering to help. I think they are just looking for a means to do this in a way that is mutually beneficial.

Senator CASEY. Thank you, doctor. Dr. Redd, I only left you 45 seconds. Dr. REDD. I will be brief.

We actually met with selected state health officials last spring to ask this exact question that you asked. Are there things that we should be doing differently to support rural health departments?

The conclusion was, it was a little bit surprising to me that the capabilities needed for rural districts and urban are largely the same: detection capability, communications, incident command or the structure to run responses. But there are additional, as you mentioned, there are additional layers of challenge with transport and access to medical care.

I think that this is an issue a little bit beyond emergency response and I think the idea of telemedicine as a tool is a great idea. But it is essentially a question of, how do we make sure that those communities have access to medical care during and not during emergencies?

Senator CASEY. Thank you, Mr. Chairman. Senator BURR. Senator Isakson.

Senator ISAKSON. Thank you, Senator Burr.

Thank you for your work on pandemics and on BARDA for a long period of time. It is very valuable. The Committee has worked on it a long time.

I appreciate Chairman Alexander and Senator Murray, and the work that they have done.

Thanks, Dr. Kadlec, for calling out the V.A.

As Chairman of the Veterans Committee in the Senate, I have learned a lot of things about our delivery system and capabilities in terms of V.A. healthcare, which is the second largest employer in the United State Government. A lot of people do not realize that, but that

is how big and pervasive the V.A. is, and they provide significant healthcare to seniors by virtue of their delivery system.

Your callout for them and what they did in Houston, Houston has appreciated it.

Also, I would say that most of the research dollars that are invested by the U.S. Government in control groups are through the V.A. because you have a control group of patients where you can do a good research sample. Our veterans, and our Veterans Administration, provide a great service in terms of that, which brings me to Admiral Redd.

You have your emergency preparedness grant that you give to the local governments. When we had the incident we had happen in Hawaii last week, where we had a false alarm on a missile attack, which was rather unsettling to the people of Hawaii and, quite frankly, it was unsettling to me. That is an emergency grant challenge you want to make sure you do not ever have with a pandemic where you get the wrong information going out from a designated agency at the wrong time.

Do we concentrate a lot on that to protect ourselves from bad information getting out on pandemics or on diseases?

Dr. REDD. I think that really gets to one of the core requirements that we have, which is to be sure that the information we are providing is as valid as it can be. And if we are not certain, but we believe people need to know, we make sure that those caveats are expressed.

It really gets to some of the basic principles of risk communication to tell people what we know, what we do not know, and what we are doing to find out those things that we do not know.

Senator ISAKSON. Dr. Gottlieb, I appreciate your mention of Priority Review Vouchers.

Senator Casey and I worked on PRV's for rare diseases that affect children and successfully passed legislation. I think the first drug has been approved now and put on PRV. It was issued by the department, and we appreciate that.

Your use of that to expand the use of PRV's to encourage the development of drugs that are either very costly to develop or hard to develop is very important.

How do you intend to use that to expand the development in terms of new pharmaceuticals?

Dr. GOTTLIEB. Well, as you know, the PRV program provides an additional incentive for manufacturers to try to develop products for these purposes. And so, I think it is one of the tools that Congress contemplated to try to address some of the challenges that we have already talked about that I mentioned, which is that sometimes this is not a typical market where you have the usual market-based incentives to try to make the capital investments to develop these products.

There is work going on to look at what impact the PRV's have had. We have implemented the program. We have seen sponsors come forward and be awarded these PRV's and sell them in the secondary market as a way to try to recoup some of the cost of the investment.

Senator ISAKSON. On that same subject, I have done a lot of work on a disease called Batten's, which is an incurable disease of young people. I had a personal situation that piqued my interest in my district when I was in the House, and I have remained interested in that.

It is a very difficult disease for which there is no cure, but with the gene therapy development and the delivery system of pharmaceuticals to specific parts of the body, and the brain in particular, there is hope and promise for that.

Do you issue guidance letters to research hospitals or research facilities to give them guidance on how they can test or develop to work on a breakthrough drug for a disease like Batten's?

Dr. GOTTLIEB. Senator, I think one of the areas of the most promise right now that we are looking on when we look across our portfolio is what is going on, as I said, with biologics with respect to cell based therapies, machine based therapies where we have the ability to cure inherited disorders, devastating inherited disorders that were not treatable just a short time ago.

We are going to be putting out this starting probably this spring, maybe a little earlier, a suite of products with specific guidance on how sponsors can address certain disorders with gene therapy to try to provide as much regulatory clarity as possible.

We are going to look at some of the more common disorders first, but we are going to try to work through some of these rarer diseases to make sure that product developers have a lot of clarity around what the pathway forward would be.

Senator ISAKSON. I commend you on the leadership you have shown in that effort already and plan to support you in any way we can to help you do that in the future.

Thank you very much. Thanks to all of you for testifying. Senator BURR. Senator Smith.

Senator SMITH. Thank you very much, Senator Burr, and Chair Alexander, and Senator Murray.

I am so pleased to be able to serve on this Committee. Thank you very much.

I would like to come back to something that Senator Murray and, I think, several others have talked about, which is the importance of a connection and support to local public health organizations.

In the past year in Minnesota, we have dealt with three infectious disease outbreaks: measles, multidrug resistant tuberculosis, and also syphilis. And all of these outbreaks have required a really immediate response, as well as a sustained response, as we have gone forward.

Minnesota has traditionally, as I am sure you know, invested heavily in emergency preparedness and dealing with infectious diseases, probably because of our history in agriculture more than anything.

But in these particular situations, the financial resources that we had were not enough and so, we turned to the CDC for support. And, of course, no fault of yours, there were no resources there.

What we did is we moved forward with the state legislature to pass an emergency public health response account so that we could respond quickly because speed is of the essence when you are dealing with these kinds of outbreaks.

My question is in what ways do you think that an emergency response fund would strengthen our federal and state efforts during an outbreak or after a disaster?

Maybe if you could just talk a little bit about that, that would be helpful.

Dr. REDD. Thank you very much.

I think that resources are critical in responding to an emergency. We had lengthy delays, both in the Ebola response and in the Zika response before funding became available, and I think that hindered what we were able to accomplish.

There has been discussion both in Congress and in the Administration about how to do that, and I think that those discussions will continue. But I think something along those lines would be quite helpful.

Let me mention one thing that we have done specifically once funds are available to make sure that they are used more quickly. We had a Notice of Funding Opportunity that we opened to our grantees through the Public Health Emergency Preparedness program and allowed them to apply for funds. There were no funds in this award, but we have an approved, but unfunded, grant mechanism so that we do not get delayed at the Federal level once funding is appropriated.

Senator SMITH. Thank you.

Dr. KADLEC. Senator Smith, if I could just add.

There exits already in authorizing language for a fund for HHS that has \$57,000 in it. Obviously, it is not an authorization problem.

But I just want to highlight the fact that, yes, there is a fund that is needed. It should be a fund that necessarily is managed by the Secretary and based on a public health emergency. There can be, if you will, distribution of funds from that, and that it can be used across HHS, or to fund states and locals in a way that would be rapid.

Obviously, there is going to be a need for, it would be like the medical equivalent of the disaster relief fund, I think. But I think there would be, obviously, a requirement to notify Congress in those sorts of situations on a basis of reporting back on some occasions to make sure the funds are being spent appropriately.

Senator SMITH. Right. Thank you.

Essentially, we need to make sure we have good accountability. Dr. KADLEC. Right.

Senator SMITH. That the funds are being spent the way they are supposed to be spent—

Dr. KADLEC. Yes, ma'am.

Senator SMITH —which I would completely agree with.

I realize that this is an authorizing question and not an appropriating discussion here, but Dr. Kadlec, if such a fund were to be made available, what would you advise in terms of the level of funding that would be necessary to have this actually be workable? Dr. KADLEC. Well, ma'am, I would have to back in a firm number, but I think what you probably looked at is what happened with Ebola or the original pandemic influenza appropriations, which are on the order of \$2.5 to \$3.5 billion.

Again, what you need to hedge is the opportunity for Congress to weigh in fully, and again, on the basis of time. So obviously, there are a lot of factors to be considered in there, but there is a rich, historical record that could probably be drawn upon to identify an appropriate level that would get us through the initial crisis to the point where Congress can basically perform its fiduciary responsibilities.

Senator SMITH. Right. Thank you very much.

Senator Burr, I was struck by what you said about how we need to stick to our knitting on this Committee and not expand too much. And also how important it is to think about the processes that we have in place with this authorized legislation, to make sure that it works well.

I appreciate your comments. I think it gives us some good food for thought as we consider how we can respond as quickly as possible when there is an emergency.

Thank you.

Senator BURR. We, again, welcome you to the Committee. Senator Young.

Senator YOUNG. Well, thank you, Chairman.

The World Organization for Animal Health estimates that roughly 60 percent of known human diseases are transmitted from animals to people. They are of so called zoonotic origin.

Every year, an average of five human diseases appear such as Ebola, HIV, and new strains of influenza; three of which are zoonotic.

In my home State of Indiana, we suffered considerable losses in the widespread bird flu outbreak, one that led to the destruction of 400,000 turkeys. And this followed in 2015 and the outbreak that led to the loss of 48 million poultry.

Dr. Kadlec, what are we doing now to prevent the spread and transmission of diseases from animals to human beings?

Dr. KADLEC. Well, sir, I have to say that, quite frankly, we need to do more.

The one health concept that you are outlining is an important one. Influenza is not the only disease that is of zoonotic importance that has pandemic potential; SARS and MERS are examples of others.

But I think I need to really defer to Admiral Redd to talk about the role of the CDC here and their role of surveillance because, quite frankly, they are on the cutting edge to ensure that you can recognize those events rapidly as they have in Iowa, I think.

Senator YOUNG. Thank you. Admiral.

Dr. REDD. Thank you, Dr. Kadlec and Senator Young.

We are working very closely with USDA on this issue and particularly on influenza. We were really joined at the hip in the response to this importation of these avian influenza viruses.

Our role was to make sure that we understood the biology and that if any human infections occurred, that those were rapidly detected and treated, and to protect workers in the process of the culling that was going on.

Senator YOUNG. You, no doubt, do the best you can with the resources and authorities you have.

No. 1, how are we doing with respect to tracking and then the responding to these situations and preparing for the next one?

Then secondarily, speak to any additional authorities or resources you might need to optimize your efforts.

Dr. REDD. I think that given the strategy that we have, which is a reactive one, I think we are doing well at detecting and containing importations.

Senator YOUNG. That predicate caught my attention. Dr. REDD. Yes.

Senator YOUNG. Given that our strategy is a reactive one. Dr. REDD. Right.

I think that the ability to prevent importation of influenza viruses that could be transmitted by migratory waterfowl, for example.

Senator YOUNG. Yes, sir.

Dr. REDD. It is very challenging.

I think there is a lot being done on the animal health side. I think that it is a challenge and the basic strategy is to identify and limit, to the extent possible, to one flock or as small an area as possible. And through that process to prevent human infection should the virus have the capability to be transmitted or to be infectious to humans.

Dr. GOTTLIEB. If I may, just for 15 seconds.

I would also talk about the importance of thinking about animal drugs in our approach. And Cures, as you know, extended the EOA authority to animal drugs. We might also contemplate trying to think about how we create incentives for the development of animal drugs to target some of these threats including maybe a break through therapy designation for

animal drugs or other kinds of creative policy approaches to make sure that that is a part of our approach as well.

Senator YOUNG. Well, thank you.

I look forward to working with each of you. I will probably have some follow-up questions I will submit in writing, and hopefully we can improve our current systems for dealing with these matters.

Senator YOUNG. Dr. Gottlieb, you just once again mentioned incentives in the animal context, but I would like to pivot to our antibacterial resistance threats.

Every year, at least 2 million people in the U.S. acquire serious bacterial infections that are resistant to one or more types of antibacterial drugs.

However, as I understand it, there are very few companies that are developing new antibiotics, and those that are focused on the most serious bacterial threats are even fewer.

Is additional action needed to immediately incentivize the development of drugs to combat this growing global problem? And if so, what might new incentives look like? And what might we do as Members of Congress to provide those incentives?

Dr. GOTTLIEB. Senator, thank you for the question.

As you know, Cures created a number of new vehicles, and some incentives, for development in this space. We are encouraged by the early interest we are seeing in those pathways, things like the LPAD pathway. I think we are going to have more information soon on how well they are working.

I mean, we can always contemplate additional policy steps, and I would be happy to talk to your office and work with you on that. I think that this is an area, to your point, that we need to think about what more we can be doing.

But Congress has done, taken some steps recently that we are very encouraged by. We are seeing a lot of good, early interest in them.

Senator YOUNG. Thank you. Senator BURR. Senator Kaine.

Senator Kaine. Thank you, Mr. Chair, and thanks to the witnesses.

I have great confidence in this Committee's ability to work on this PAHPA reauthorization in a bipartisan way. I have two observations and a concern. So an observation is this and some of you have alluded to it, and Senator Isakson's questions alluded to it. One of the tasks of emergency preparedness is to prepare for attack, and you have talked about chemical and biological. Senator Isakson talked about the incident in Hawaii this weekend.

I just want to say for the record and for the public. The prospect of nuclear war is being discussed with a lot of frequency in this building to a degree that I have not seen in the time I have been in the Senate.

I am on the Armed Services and Foreign Relations Committees. We have had a series of hearings, even open, where there has been discussion about the prospect of land war on the Korean peninsula. We had an Armed Services hearing recently where a witness volunteered in public—and it was sort of a non sequitur, why he would bring it up as a Member of the Administration—about what the likely cost of reconstructing Kansas City would be after a nuclear attack.

I noticed an article in "The New York Times" a few days ago. "The C.D.C. Wants to Get People Prepared for Nuclear War." That was supposed to happen yesterday.

"On January 16, the Centers for Disease Control and Prevention will present a workshop titled 'Public Health Response to a Nuclear Detonation,' for doctors, Government officials,

emergency responders, and others whom, if they survive, would be responsible for overseeing the emergency response to a nuclear attack.”

Quote, “‘While nuclear detention is unlikely,’ the C.D.C. stated on its Website, ‘It would have devastating results and there would be limited time to take critical protection steps. Despite the fear surrounding such an event, planning and preparation can lessen deaths and illness.’

Quote, “‘Join us for this session of Grand Rounds to learn what public health programs have done on a Federal, state, and local level to prepare for a nuclear detonation. Learn how planning and preparation efforts for a nuclear detonation are similar and different from other emergency response planning efforts.’ ‘That is off the CDC Website.

The article goes on to say, “The agenda for the day includes, ‘Preparing for the Unthinkable,’ to ‘Roadmap to Radiation Preparedness,’ and, ‘Using Data and Decision Aids to Drive Response Efforts.’

I understand the CDC rescheduled that, canceled it from yesterday, and had a roundtable on the flu instead, but this is a realistic discussion about these prospects. And then add to it the “Dr. Strangelove” like incident over the weekend where a state sent out a mass e-mail telling people there was a ballistic missile incoming to Hawaii, which occasioned 38 minutes of panic.

Then on Tuesday, the Japanese state broadcaster, NHK, put out a warning that North Korea had fired a nuclear missile and urged Japanese citizens to take cover. That was retracted within a very few minutes.

There is a lot of discussion, some very intentional and some frightening, about the prospect of nuclear war that is happening, and this is in the provenance of your agencies.

I just want to put that on the record that that is sort of a normal area for discussion these days. I find it incredibly frightening and the normality of it I find incredibly frightening.

The second observation I want to make is this. This is a discussion about national security. We are involved in a budget debate right now. Right now, the spending bill ends January 19 and one of the points of argument is whether we might fund defense accounts over the budget caps of nondefense accounts.

You are about national security. You are about national defense and all of your agencies are funded through the nondefense accounts of the Federal budget.

Any suggestion that we would increase defense budgeting, but hold the line and put nondefense agencies subject to their caps, would not really fund the national security priorities that you are here about, and that is something we have got to grapple with.

Here is my question.

I am very worried about this Hawaii incident because in a time of heightened tension, we know from history that wars often start accidentally. There is a miscommunication and a misunderstanding; there is an overreaction. That is how World War I started. That is how most wars start.

I know there is going to be a hearing later in the week, I think, on the House Armed Services Committee about this. I am sure that there is an investigation at the state level. But part of the responsibility—and Dr. Kadlec, I guess this is mostly directed to you—part of the responsibility in the emergency preparedness and response side is accurate communication. As a former mayor and Governor, that depends heavily upon communication between Federal, state, and local officials.

As you approach this thought of thinking about reauthorization in this climate where things can sometimes be pretty tense, how do you look at that state, local, and Federal coordination effort, especially as it deals with the communication of accurate information, and knocking down inaccurate information?

As quickly as you can.

Dr. KADLEC. Well, sir, we take it very seriously, No. 1.

No. 2 is the experience we had with the hurricanes, particularly Hurricane Maria, I think, highlighted some of the challenges. In my testimony, I identified some of the incident command issues that we have to address, which really is not only information out, but information in.

I think the issues that we need to work with—not only with our CDC brethren, but with state and local authorities, as well with FEMA; I met with them just as of yesterday—talking about, how do we integrate our efforts closer so that we have better information exchange on these kinds of issues? Whether they are hurricanes, pandemics, or whatever it is that, quite frankly, you need to kind of think through, learn through not only experience, as we did with the hurricanes, but exercises, as we did.

Sir, just to highlight one thing, since I have been around the block on these sets of issues. Going back to 2000, it has been a routine practice in the U.S. Government, the Federal Government at least, to exercise the idea of a nuclear detonation. Most concerning then was terrorism as a matter of an improvised nuclear device.

It is not necessarily new. Obviously, the context is different.

But I think the point here, though, to your issue is it does require a closer lash up with our Federal partners on these issues to make sure that we have good cross lateral, horizontal flow of information, as well as with our state and local folks.

We are investigating with FEMA just as another example of how we can basically work together in bed both our health and disaster people in state and local state EOC's to, again, work more seamlessly with our state colleagues.

We are looking at all kinds of options right now to that effect. Senator KAINE. I appreciate it.

Mr. Chair, thank you for letting me go over.

I hope you will follow the investigation of the Hawaii incident for your own purposes because for purposes of having good information and that coordination, I suspect there will be some lessons that will come out of that that would be relevant to other circumstances as well.

Thank you, Mr. Chair.

Senator BURR. Thank you, Senator Kaine. Senator Collins.

Senator COLLINS. Thank you, Mr. Chairman.

I want to applaud you for your leadership in this area.

More than a decade ago, we established a Port Security Program that led to radiation portal monitors being installed at our major ports so that they could screen incoming and outgoing cargo, trucks, and individuals for radiological material.

I contrast that port security effort with what I perceive to be a real vulnerability in our ability to detect and effectively and quickly respond to an attack using biological or chemical agents.

Dr. Kadlec and Dr. Redd, I would like you both to address the level of preparedness that we have to respond and detect, first of all to detect, a biological or chemical attack and to respond to it. I would like specifically to know whether cities

have used some of the Federal funds that the Admiral referred to, to install sensors that would be able to detect these agents.

I would also like you both to comment on the preparedness of our hospitals to cope with the victims of a biological or a chemical attack.

I remember being in Israel many years ago and being so impressed with their preparation and their ability to convert their hospitals to respond to that kind of attack.

Dr. Kadlec, why do we not start with you and then Admiral Redd?

Dr. KADLEC. Thank you, Senator Collins. I think one of the issues, and again, I have some insights on this historically.

But currently, the biologic program run by the Department of Homeland Security provides area protection for cities. So I think there is a real desire.

I have met with the new WMD, I do not know, directorate, Assistant Secretary over at DHS about improvements we can make to our chemical and biological attack kind of detection.

Quite frankly, our capabilities are fairly still limited and primitive, quite frankly. And I think there is a sincere desire on the part of DHS and HHS between ourselves to basically do improvement to do that.

To your second issue, how well prepared we are. Certainly, we have a Strategic National Stockpile that can address many, but not all, of these threat agents. So there is work to do there in terms of some of the development and procurement we need to do on those issues.

But one of the critical areas that collectively the CDC and our office are considering is really on the last mile of distribution.

As mentioned by Senator Murray, we can move Strategic National Stockpile resources anywhere in the country within 12 hours. The question is from that point forward getting it into the hands and into the mouths of every American person who is at risk is a significant challenge that, I think, collectively, we need to work on.

But now, I will defer to Admiral Redd for his comments.

Dr. REDD. Thank you. I think this is a really important question. If we are attacked in this way, the effectiveness of our response will depend on the speed and the scale with which we respond.

I think that the way that a biological attack would manifest itself would probably be different than a chemical attack. A chemical attack would primarily require a local, a near-instantaneous local response.

The CDC's Strategic National Stockpile has deployed antidotes for nerve agents. Over 1,000 different locations have pallets of these antidotes that are available to supplement the treatment that would be available immediately.

We also have and getting ever better capability to determine exactly which toxin has been used. So there is a laboratory element that the CDC is also responsible for.

On the biological side, we have made great strides with the laboratory response network. Every state has at least one laboratory that is able to use advanced techniques to diagnose these infections. There are a total of 150 laboratories around the world, including laboratories that can test food, can test water, and environmental samples from animals.

So looking to the future, the technology of whole genome sequencing is something that we need to continue to push out that would allow very rapid——

We talked about faster and more accurate. This is actually more information than we can get from current technologies; things like resistance to antibiotics or relationships of certain organisms to other, “where did it come from?” kinds of questions.

Senator COLLINS. Thank you.

Dr. KADLEC. Ma’am, can I just add one thing? Senator COLLINS. Yes.

Dr. KADLEC. To your question about how our hospitals would do. Senator COLLINS. Yes.

Dr. KADLEC. I think it was noted by the Chairman that even a bad flu seasons, as the current one we have, is overwhelming our hospital system.

Senator COLLINS. Exactly. That is one reason that I asked the question.

Thank you.

The Chairman [presiding]. Thanks, Senator Collins.

Senator Jones, welcome. We are glad to have you a part of this Committee. I acknowledged your new membership a little earlier, but we are glad to have you here. This is a Committee that has many different points of view, but works well together. So this is another subject that we intend to have some bipartisan success on.

Senator JONES. Thank you.

The CHAIRMAN. Senator Warren.

Senator WARREN. Thank you, Mr. Chairman.

So we are here today to talk about PAHPA, the framework for our response to all sorts of emergencies: natural disasters, accidents with hazardous materials, terrorist attacks, pandemics, you name it.

I returned, just a few days ago, from a trip to Puerto Rico and I know some of my colleagues have also been to Puerto Rico recently.

During my trip, it was clear that nearly 4 months after the storm, the crisis in Puerto Rico is a daily reality for tens of thousands, hundreds of thousands of people.

Dr. Kadlec, you are the top official in charge of preparedness and response at HHS. What is the biggest thing you have learned from the situation in Puerto Rico and the U.S. Virgin Islands about how we need to strengthen our preparedness and response capabilities?

Dr. KADLEC. Well, thank you, ma’am.

I think there are a couple of levels to go here.

One is improving the resilience of our innate hospital healthcare structure. That is one area.

The other thing is really the resilience of our public health system, which is a separate piece, but a related piece.

In Puerto Rico in particular there were, in the initial stages— after that terrible devastation that literally devastated the whole island and every life was touched—it was very difficult for the local public health and medical infrastructure.

There are some incredible heroic stories of doctors, nurses, laboratorians who basically responded, public health officials, who left their families, left their houses in disarray and basically went to respond to help their neighbors and their communities. But I think that is one piece of this that needs to be addressed, what happens before the storm.

The second piece is, how quickly can we move in? We had deployed teams to Puerto Rico in advance of both Irma and Maria to be available once the storm passed, both storms passed, to basically respond quickly. But even so, with the level of devastation, that was a huge piece of it. And a huge piece of it was the lingering devastation, not only the loss of

communications and electricity, but also the damage to the ports and the airfields that limited some of the movement.

So I think one of the lessons learned was you want to go in aggressively before the storm, if you can. We literally put peoples' lives at risk from our response teams, including people from Massachusetts, Massachusetts One, that responded to all three storms.

Senator WARREN. Yes.

Dr. KADLEC. They are great people and, again, representative of your constituents from other states around the country that responded.

But also, there is a piece of this that we have to somewhat remove some of the dependencies in the responses. Seeing how we can move quicker and faster, if that is possible. A lot of it was dependent on being able to transport through air or barge, again, responding to an island is a tough one.

Senator WARREN. So I appreciate this and I am glad we are trying to think about what we need to do and what we need to do better, and to acknowledge heroic efforts, but we need a better structure here.

But to apply these lessons, we also need good data. We need to know not just what we got right or what we got wrong, but when we got it right, when we got it wrong, by how much, and what kind of difference it would make on the ground.

One of the things that struck me during my trip last week was how sketchy the data are. For example, I met with the Federal and Puerto Rican officials at FEMA's field office and they said, "No more issues with potable water." No waterborne diseases, all the water is drinkable. And I asked this specifically. Turn on the taps. You hold a glass under it. The water will be drinkable, is drinkable, everywhere on the island. It sounds great.

Not so much though.

I met with the Massachusetts State Police volunteers who told me that they had observed raw sewage in the water. At the public health center that I visited in Loiza, they said they still do not have potable water, no drinkable water for their patients. They said they serve 100,000 people and that none of them have drinkable water.

We heard the same kind of contradictions when it came to statements about how many people lacked power.

Dr. Kadlec, I get that public health emergencies are really challenging circumstances, and it is hard to get good data. But how does HHS and other agencies collect data in a way that is reliable so that you can deploy your resources effectively, hold yourselves accountable to get the job done that needs to be done?

Dr. KADLEC. Well, ma'am, we learned a lot from the experience in Puerto Rico and we are trying to rectify that.

Because of the loss of communications, cell towers, and the like, the ability to get information either from local authorities or local hospitals or clinics was practically nil.

We literally went to the point, at one time, to basically use runners from the National Guard who would have satellite phones to basically go to hospitals and clinics to report information out.

But that is a major consideration and lesson that we are still learning that we have to address because it is a major shortfall. Because if you were to add, again, a terrible event like this, a terrible earthquake or a nuclear or radiological event, you could imagine that the circumstances would be even more challenging.

But that is an area of great, intense concern, quite frankly, and work that we have to do.

Senator WARREN. I am very concerned about this and I do not have time. I am out of time now, so I cannot ask Rear Admiral Redd and Dr. Gottlieb about their work in Puerto Rico.

But Senator Cassidy and I sent a letter to Chairman Alexander signed by seven other Members of this Committee asking for a hearing on the recovery efforts in Puerto Rico and the U.S. Virgin Islands, and I hope we will be able to hold that hearing.

Puerto Rico might not be on the front pages anymore, but it is a humanitarian crisis and we have a moral, and a constitutional, responsibility to exercise oversight responsibilities here. Thank you.

Thank you, Mr. Chairman.

The CHAIRMAN. Thank you, Senator Warren. Senator Cassidy.

Senator CASSIDY. Well, thank you.

Dr. Kadlec, I am going to put you on the payroll, man. Earlier, you were responding to Senator Smith regarding a possible bill. We have that bill.

The Public Health Emergency Fund, actually stimulated by conversations with Dr. Frieden. He said that in the Ebola crisis, “There were ten different authorizations that had to be signed off on,” before he could get somebody to travel immediately to Africa. Kind of crazy.

And, “I kept on contrasting the authorization process we were going through, which was cumbersome and slow with that before and after Katrina.” Before Katrina, FEMA had to come to get the initial dollars. After Katrina, Congress recognized that is not the best way, so there is a pot of money that can immediately be accessed. And if it goes over that, then they come back and get another authorization.

Senator Schatz and I have put together a bill that, one, waives these contracting requirements for that immediate period so you can actually deploy people.

Second, based upon—and Dr. Kadlec this is where you nailed it—the previous 14 years of public health emergencies, we take the average of that expenditure and we make those dollars available upfront to be immediately drawn down.

Still accountability; GAO is going to do a report and make sure that the CDC has not used it to go to Hawaii for a conference as opposed to Africa to fight Ebola. No offense, Dr. Redd. But still, the point being that we would have the accountability built in, but we think it is a good bill.

Now, let me move onto something different.

Dr. Redd, I was struck speaking to people after Zika hit that in retrospect—and of course, everything in retrospect, if I could do things in retrospect I would be a millionaire on the stock market—but in retrospect, you could have predicted what was going to happen because supposedly Brazil was flying in folks from the South Pacific to work on their Olympic stadiums that Zika had been breaking out in the South Pacific where these workers were coming from. Brazil is like a Petri dish for Zika, and you could have predicted it.

Now, of course, it is retrospective. But the thought occurs to me with Big Data, we can actually put in travel patterns. We can put in areas of receptivity. We can put in where there are outbreaks and make some, at least, first blush guess as to where the next epidemic is going to be.

Is that just me, “would that not be great,” sort of thing or is this something practical? And if it is practical, is the CDC doing it?

Dr. REDD. I agree with your overall statement.

I think another way of looking at this is that the pathway that Zika followed was very similar to Chikungunya just a few years before where it existed in the Pacific and then caused big outbreaks in Brazil and South America.

Another point that is the same is when we had outbreaks in the Caribbean, we knew locations of lots of travel to the U.S. and where the vector was, the *Aedes aegypti* mosquito lived. It is the same place that we have seen small dengue outbreaks in the past. Senator CASSIDY. So, can we use this predictively? Because if we could use it predictively, if we could see, “Well, Brazilians are going to be having this problem. Let us go down there and encourage them to spray for mosquitoes,” et cetera. Dr. REDD. I think it is hard to do that.

I think that the vector is very resilient and there were some questions——

Senator CASSIDY. Now, I was just giving the example of spraying the mosquitoes as a concrete action. But what I am asking about is not the vector of resilience.

Can we use Big Data just to look at travel patterns where there is an outbreak and guess where there might be a spread of such an outbreak?

Dr. REDD. I think we can. I think the challenge is what do you do with that information. And is there a way to use that, for example, to have prevented the Zika outbreak in Miami-Dade County?

I think that the things that you do——

Senator CASSIDY. So you were ahead of us. What you use the information is different than if you can actually acquire the information.

If it is practical and right, if you will, to acquire the information, are we putting such systems in place?

Dr. REDD. Well, just to take the Zika example, there was a lot of communication with Texas and Florida, Louisiana, the Gulf Coast areas that have the *Aedes aegypti* mosquito recognizing that——

Senator CASSIDY. Okay. You are still after me because that is after it hit Brazil and after we knew that there was going to be travel from Brazil up.

I am actually trying to go proactively before that in that we could see the Brazilians were bringing in lots of workers from the South Pacific and therefore, it was predictable that whatever was breaking out there was going to breakout here.

Now, that is taking the battle to the enemy, if you will. Are we doing that?

Do we have a worldwide kind of map—and I have seen such a map of hotspots of infectious diseases—overlaid with travel patterns to guess whether or not? And I understand the CDC has worldwide outposts.

So again, I am asking something closer to the point—— Dr. REDD. Sure.

Senator CASSIDY ——than whether it gets to Texas.

Dr. REDD. I think the quality of information is variable. I do not think we have——

For example, I think the information we have about influenza is much better than we have about all the vector-borne, all the mosquito-borne diseases that are out there where we know what viruses are circulating in China because of the known importance of influenza and the risk it poses for a global pandemic.

Senator CASSIDY. Now, I have seen maps—and I am overtime, and I will stop after this—but I have seen maps put out by the CDC and the World Health in which it shows, “Oh, yes. Here is this and there is that.” And it is a hotspot of a particular virus.

Can that not be, again, overlaid with travel patterns?

Dr. REDD. Well, there are parts of the world that some of the discussion earlier about the number of zoonotic diseases that are detected that cause infections in humans, there are certain parts of the world that are more prone to those emergences.

I think, again, your question is, how do we use that information? We certainly do have travel maps of where people travel to and from. We have information about where various diseases occur at variable degrees of granularity. I think those two things do go together.

I think how we would use that to take a preemptive action is really, I think that is the question that you are getting at.

Senator CASSIDY. Okay. I yield back. The CHAIRMAN. Senator Murphy.

Senator MURPHY. Thank you very much, Mr. Chairman.

This is incredibly informative. Thank you to all of the witnesses. I want to raise two concerns that I have emanating from conversations I have had with companies in Connecticut that operate in the pandemic response field.

The first is regarding response to an influenza outbreak and this is for either Dr. Kadlec, I think, or Dr. Redd.

Dr. Kadlec, in your testimony, you write that we have sufficient domestic vaccine manufacturing capacity to produce a bulk vaccine for every American within 6 months.

But I want to ask either of you about the question of vaccine delivery. This comes from conversations with a manufacturer in Connecticut, BD, which is one of the bigger syringe manufacturers.

My understanding is that if you needed to get a vaccine to everybody, you would need about 600 million drug delivery devices. Now, BD is one of the biggest manufacturers, but it would take them 6 years to do 600 million units.

What are your thoughts on preparation to make sure that we not only have the right amount of vaccine, but the right amount of vaccine delivery devices?

Dr. KADLEC. Well, thank you, sir.

That is one of the issues, and then problems, that has to be addressed, quite frankly, and I have my Director from BARDA, if he wants to make a comment. He is welcome to at this point.

But I think part of the strategy we are looking at also is, how can we innovate and either have better delivery devices? Or specifically, can we make better vaccines that only require one dose? Remember, the 600 million doses are for two per person.

The third thing is there are maybe new vaccine technologies that allow you to do it orally, or intranasally, or a variety of other means beside subcutaneously with a needle. So I think all those issues are being evaluated and pursued.

But yes, there are some very significant shortfalls and there are other disposables as well that are a matter of concern when you get into that kind of circumstance.

Rick, do you have anything? Senator MURPHY. I am sorry.

Dr. KADLEC. I just wanted to make sure if I left something out, if Dr. Bright could offer it.

Dr. REDD. I think this is a modeling problem. Particularly from the supply standpoint, making sure that we are tapping into the existing commercial market, and we are able to leverage that system in addition to stockpiling what that market cannot produce.

Senator MURPHY. Dr. Kadlec, back to you, and my second concern.

BARDA, as we have talked about, is such a wonderful model and working with industry, you have developed 34 approved medical countermeasures, 23 influenza vaccines.

Again, coming back to a company that BARDA has worked with in Connecticut, Protein Sciences, which as you may know, has come up with an innovative way to develop a vaccine; not the traditional egg-based vaccine, but a recombinant DNA technology mechanism. They raised the issue of how you make sure that having spent the money to develop these vaccines, there is a market so that they can continue to develop processes and make sure that they are available.

What is the responsibility of BARDA, or HHS or, I guess, if the CDC wants to weigh in, on how you make sure that the money being spent on research ends up on a marketable vaccine? And that you are working with companies to make sure that a bridge market exists so that they are available in the case that you need them for a pandemic.

Dr. KADLEC. Well, clearly, that is one of the factors that goes into this public-private partnership. And I would also invite Dr. Gottlieb because it has been the case with the PRV's, like with the vouchers, if you get through that you can get some benefits. But we need to look at the whole variety of incentives to not only get companies into the market, but keep them in the market and keep them viable going forward.

There is this issue of "the second valley of death," which has been raised at some point in time that once you have delivered your vaccine—and if you do not get either the opportunity to replenish or use that technology for some other commercial purpose—that the company may still be at risk, and you may still basically be confronted by the limitations that you do not have the producer. So these are issues that are still pretty thorny and, quite frankly, that is one of the areas, I think, that probably deserve a little more consideration during your reauthorization.

Senator MURPHY. I do not mean to keep Dr. Gottlieb out of this conversation.

You raised this in some of your earlier testimony, some of the market disincentives here and I would love to hear your thoughts. Dr. GOTTLIEB. Yes, I think you raise a very valid point, Senator. If you are talking about a countermeasure that does not necessarily have a dual use for another public health application, your only market is going to be in preparedness and presumably the only market is going to be for stockpiling. And if it is not something that turns over a lot, so you are not going to have to constantly replenish your stockpile.

Depending on what you are developing, the cost of capital to try to develop that product might be too high to justify the investment. I saw this when I was on the other side of this equation.

We have tried to offset some of that with the PRV's, but I will say that the value of the PRV's in the marketplace have diminished as we had more PRV's. So the value of the incentive has also gone down over time.

So I think this is something we should all contemplate. Senator MURPHY. Thank you.

Thank you, Mr. Chairman.

The CHAIRMAN. Thank you, Senator Murphy. Senator Murkowski.

Senator MURKOWSKI. Thank you, Mr. Chairman. Appreciate the discussion here this morning.

Dr. Kadlec, you recognized, in response to Senator Warren's question, the challenge that Puerto Rico faced after the devastating hurricanes. I mean, it is difficult in an island area where you are not connected, where you are remote.

Well, that brings it close to home to me. We are not an island in Alaska, but we are not connected to the continental United States, and we are really big, and we do not have a lot of

roads. It was just about 75, 78 years ago that we had a diphtheria outbreak in Nome and we were able to deliver the serum by dogsled.

We are not doing that anymore, thankfully.

But it does speak to the reality of how to respond when you have an outbreak, and your ability to move in quickly is limited either because of weather or just access limitations.

We were reminded of this at 9/11 when all the airspace was shutdown, when you now have 80 percent of your communities that have no way to get things in and out. A major earthquake that can take out a major port that serves access or airports. And so, for us particularly in Alaska, we had to be our own little island when it comes to response.

But when you are trying to get stockpiles of vaccines or the like, that makes it very, very challenging. And I do not recall whether it was you, Dr. Kadlec or Admiral Redd, mentioned that you can get stockpiles, I believe, of vaccines anywhere in the United States within 12 hours.

Did I hear that correctly? [All nod in assent.]

Senator MURKOWSKI. Should I be worried in a small, remote, not accessible by road, shut out by weather? We cannot even get a state trooper in for 3 days into certain of our villages at certain points in time.

What can you do to assure me that we can be that responsive in our more rural areas? That is one part of the question.

The other part is when it comes to infrastructure itself.

Several years back, we had the first sizable cruise ship going through the Arctic. We had all kinds of emergency preparation drills and it was not because we were most fearful of an oil spill from a ship that might hit the ice. But an issue on a ship where you now have 500 passengers who need some level of healthcare and there is no healthcare facilities to be had in the region.

So for purposes of how we can be responsive when there is a public health crisis, whether it is an outbreak or some kind of a disaster, manmade, natural, or otherwise, what assurances can you give us from these rural states?

I will turn to Dr. Kadlec and you, Admiral. Dr. KADLEC. Well, thank you, ma'am.

That is a challenge. I think the reality is the Strategic National Stockpile can get anywhere to be delivered to the state authorities within 12 hours.

Senator MURKOWSKI. So that would get to?

Dr. KADLEC. To Anchorage, for example. And then, it is really the state's responsibility to basically get those products, or those vaccines, or drugs to the last terminal mile to those people who need them.

That is an issue, quite frankly, I think ASPR and the CDC share concern, that that is an area where concerted work has to be done because there are other places in the country that probably would have similar challenges.

Admiral Redd, do you want to?

Dr. REDD. Yes, I think this is a very challenging scenario and I think that if it were a challenge to move product to a location, there would be other challenges as well; understanding the problem of the disease in that location.

We might have telecommunication, but access to laboratories, access to epidemiologic investigation, those would also be things that would be limited.

I think this probably needs to be thought of as a broader set of capabilities that are needed to assure the protection of these populations. Not just the stockpile, but medical care and really situational awareness as to what is happening in those locations.

Senator MURKOWSKI. Well, and it is something, of course, that we clearly think about.

The last thing I am going to leave you with. The State of Alaska just conducted an Alaska Health Impact Assessment. It was a framework based on the current National Climate Assessment predictions and the impact to Alaska as a state that is seeing the impact of climate change as warming temperatures. You might not feel it here on the East Coast, but it is warmer back home.

It outlines some of the potential health effects that could be coming our way several decades out. We recognize that.

But one of the concerns, of course, is infectious diseases that are particularly associated with vector borne. Usually, we are able to freeze those nasty mosquitoes and they cannot move these levels of outbreaks.

But it is something that, as we think about public health emergencies, we are so focused on the here and the now, and the disaster of the day, but I do think it is important that we be thinking long term about the changes that might be headed our direction.

Thank you, Mr. Chairman.

The CHAIRMAN. Thank you, Senator Murkowski. Senator Jones.

Senator JONES. Thank you, Mr. Chairman.

Once again, thank you for your kind welcome to this Committee. To kind of follow-up on, I think, Senator Casey may have highlighted it and Senator Murkowski was talking about the rural health areas.

I can understand the challenges when there is a pandemic and you need to get access, but I have a state that is also very rural, but we have roads. We have the ability to get serum in and things like that. But yet, we are in Tornado Alley. We are in Hurricane Alley. It comes through.

My concern is the preparedness for healthcare delivery on an immediate basis when you have those disasters because in Alabama, like so many other states, rural healthcare is disappearing, and that is a real challenge.

So I would like to have you address what is being thought about, what is being done to prepare for those types of emergencies for those communities that do not have the daily healthcare that they have got, so that immediate healthcare needs can be given to them. Dr. KADLEC. Sir, I would just say one of the areas I touched in my written testimony is on this idea of creating a National Disaster Healthcare System, really taking advantage of the nascent trauma system that we have in our country that clearly needs to be amalgamated or, if you will, kind of unified.

We would like to basically use the Hospital Preparedness Program as a means to do that. It certainly would need more resources to do that. But basically expand the regional coalitions to not only cover states, but regions, Mississippi, Alabama, that part of the country where you can actually share resources and basically do better coordination, mutual aid in those kinds of situations. Build the kind of relationships where you know about bed availability, work with the EMS systems in terms of transportation to basically identify the appropriate places to take people with different injuries or different kinds of casualties to the right place to ensure their survival.

There is a lot that can be done and quite frankly, we think by regionalizing this will help. Because Alabama has a few major cities, Mobile, clearly there are some great facilities there, as well as other parts of the state, as well as adjacent parts in Mississippi. If you can build that coalition on a regional basis, you can probably address some, but not all, of those issues.

Dr. REDD. This is a little bit beyond preparedness, but one of the things we had done at the CDC is to examine rural health. The way that we have done that as a first step is to actually examine the data that we have.

There are a series of publications on issues related to rural health in our in-house journal, “The Morbidity and Mortality Weekly Report,” and we would be happy to get those to you to define the problem.

Senator JONES. Okay, that would be great.

I also was going to ask a similar question about citizens with disabilities.

Do you have specific guidelines, things that you do to take care of those with disabilities, whether it is a physical disability, a mental disability, or whatever?

Dr. KADLEC. Sir, we have a program at HHS and the ASPR that basically uses CMS data, Medicare data to basically identify people in different regions or in states by ZIP Code, by home address, even by phone number to identify people who are dependent on durable medical equipment.

So in advance of a hurricane, for example, we provide the states, like in the case of Florida and, I believe, in Alabama too prior to Norm, before that hit that we identified people who would be at risk to power outages or who need probably special assistance if they needed to be evacuated. That is one piece of the problem.

Quite frankly, we do not have that data from Medicaid from individual states. So that would be another way to enhance that if we could get data on that.

But that is just one way to basically preidentify people at risk and it goes a long way to basically take care of folks.

Senator JONES. All right.

Dr. REDD. Just three quick things. Senator JONES. Sure.

Dr. REDD. We require our state grantees to include a section on vulnerable populations in their emergency response plans. So that is one thing.

The second is that we work with professional associations—predominantly, I am thinking more of the American Academy of Pediatrics, the American College of Obstetrics and Gynecology—when there is an emergency to make sure that we are addressing those populations.

Also, when we activate our operations center for an emergency response, there is a functional desk on vulnerable populations to try to deal with the kinds of issues that come up.

Senator JONES. Great, thank you. Thank you, gentlemen. Thank you for your testimony.

Thank you, Mr. Chairman.

The CHAIRMAN. Thank you, Senator Jones.

Senator Casey, do you have any questions or concluding remarks you would like to make?

Senator CASEY. Mr. Chairman, just some concluding remarks, and I will read through them quickly.

I want to thank our witnesses, obviously, for their insights and expertise today and their ongoing as part of the Federal Government to develop and maintain the necessary public health preparedness capabilities.

I will have some questions for the record in addition to the ones I asked already.

Senator CASEY. Next week, we look forward to hearing from non- governmental stakeholders about how we can continue to strengthen our readiness for future public health emergencies and keep the American public safe.

As we heard today, preparedness is continuous and must evolve to face new and different types of threats. I remain committed to ensuring we sustain the progress we have already made in preparing for public health emergencies, while continuing to work to anticipate the next threat.

We have a strong, bipartisan history of working together on this Committee to improve our communities' ability to respond to all manner of public health threats, and I look forward to continuing that tradition in the months ahead.

Mr. Chairman, I want to thank you for your work on this, as well as Ranking Member Murray and Senator Burr, of course.

Thank you.

The CHAIRMAN. Thank you, Senator Casey.

Senator Casey is exactly right. This is one of the many areas that this Committee has effectively worked on, both in the authorization and reauthorization of legislation to prepare our country for the unexpected disaster that might occur to us.

A lot of progress has been made and I want to thank Senator Casey and Senator Burr, especially, for their leadership over the years in this area.

As he indicated, we will be having our second hearing on this topic next Tuesday, January 23 working with Senator Murray, Senator Casey, Senator Burr, and others. We hope to be able to write legislation revisiting this Act, and mark it up in Committee this spring, and present it to the Senate for bipartisan action.

I thank the witnesses for coming today. The testimony has been very helpful. The attendance has been good.

The hearing record will remain open for 10 days. Members may submit additional information within that time, if they would like. The CHAIRMAN. Our Committee will meet again tomorrow on a different topic at 10 a.m. for a hearing entitled, "Reauthorizing the Higher Education Act: Financial Aid Simplification and Transparency."

We have been working for more than 4 years on taking a new look at the Federal Government's relationship to our colleges and universities. There are 6,000 of them. Our major role is that we appropriate about \$34 or \$35 billion a year in grants for students to attend colleges. There is more than \$100 billion of new student loans each year.

In connection with all of that money, there is a lot of opportunity and a lot of need for us to take a look at accreditation, innovation, simplification, getting through the jungle of red tape, another whole set of activities.

That will be our major focus during this year and we hope also to have that bipartisan legislation to the Senate floor sometime this spring.

Thank you for being here today.

The Committee will stand adjourned.

[Whereupon, at 12:08 p.m., the hearing was adjourned.]

Chapter 490

THE DILEMMAS OF THE LOCKDOWN: A SOCIETY IN POST COVID-19 DAYS

Maximiliano E. Korstanje*

University of Palermo, Argentina and CERS, University of Leeds, Leeds, UK

ABSTRACT

This preliminary chapter introduces readers to the content of the book; so to speak an editorial project oriented to discuss the durable effects of the global pandemic (COVID-19) in society. Although a whole portion of studies, books and publications aimed at exploring the economic consequences of the virus, less attention was given to the social maladies – i.e. racist and separatist discourses, violence and phobias- the COVID-19 certainly generates. The COVID-19 potentiates the fear of stranger closing the West in a philosophical dilemma. All restrictions and travel bans that nation-states dispose for stopping the contagion inscribe into a process that political scientists know as the “securitization process”. The present chapter holds the thesis that COVID-19 affirms a tendency originated in 9/11 which accelerates the death of hospitality. In the new normality, the “Other” has become an *undesired guest*.

Keywords: death of hospitality, west, COVID-19, terror, society

INTRODUCTION

The COVID19 left incalculable financial losses, as well as human deceases, changing not only the geopolitics but gridding the global trade into an unparalleled halt (Sheridan et al. 2020). The global pandemic shocks directly the world while evincing the material asymmetries and inequalities culturally enrooted in the postmodern capitalism (Ali, Asaria and Stranges 2020; Matthewman and Huppertz, 2020; Black 2020). Sociology of COVID19 remains in its infancy. Some voices alert on the end of capitalism, at least as we know it

* Corresponding Author’s Email: mkorst@palermo.edu.

(Zizek 2020). To date, it is very hard to precise the evolution of the pandemic. At the end of December of 2019, the Western audience captivated by the news coming from China revolving around a new virus outbreak originated in Wuhan city. Doubtless, this new virus, which is known as SARS-CoV2, gradually becomes in a global pandemic infecting more than 93 million peoples and causing more than two millions of deaths (numbers updated at 15 January of 2021).

Although governments suddenly disposed of radical measures such as the closure of borders, airspace without mentioning the imposition of strict lockdowns the virus showed higher transmissibility. Over the recent decades, the West faced similar crises associated with SARS, Ebola and Swine Flu, but nothing like COVID19 (Richardson et al. 2017). The virus disseminates rapidly because of the mobile infrastructure of the Western Hemisphere which connects far-away cities in hours, as well as the overcrowding that characterizes the urban areas (Adey et al. 2014; Lapointe 2020). To enumerate some mediate consequences of the pandemic we come across with discourses of racism or chauvinism directed against Asian tourists (Mostafanezhad and Cheer 2020), geopolitical tensions (Lee and Haupt 2020), without mentioning political crisis and turmoil derived from the economic crisis (Rogerson and Baum 2020).

The mass transport means, as well as the tourist travels, were the key factors that allowed a rapid propagation of the virus worldwide. Although sociologists and colleagues of different pundits have captivated by the advance of COVID19, less was known about its aftermaths. Sociologists are often educated to study social phenomena in normal conditions, but few voices are experts in *disaster studies*. As Enrico Quarantelli puts it, a disaster denotes the idea that the normal conditions of existence that make the life possible in society are temporal suspended or simply disappeared. Any state of disaster speaks of the incapacity of society to give a valid response to external or internal danger, in which case the social order is in jeopardy. The question of whether of disaster interrogates furtherly our vulnerability as well as the existent deficiencies to deal with urgent matters. In fact, post-disaster manuals never apply at the best as they were written when the disaster takes hit (Quarantelli 1988; 1997; 1998). Of course, this is the case of COVID19. The invitation of a leading worldly publisher as Nova Science Publisher to edit a book with a focus on COVID19 was a brilliant idea we – jointly to Argentinean philosopher Adrian Scribano- will not waste. Also, we started to work in the selection of authors who come from different latitudes and cultures. To avoid the Anglo-centrism which marks the pace in social science, we invited scholars who are not native English speaker. This seems to have some limitations because of the grammar barriers, but we bet it worth our times. The present (short) chapter discusses the long-durable effects of COVID19 in society while discussing the different chapters that form the present book while lays the foundations towards new paradigms to understand the effects of the pandemic in postmodern society.

COVID19, SOCIETY AND POLITICS

In a seminal paper, which entitles *sociology of COVID19*, Steve Matthewman and Kate Huppatz (2020) locates the COVID19 in the epicenter of the most serious health and economic crisis of human history. Global citizens who were accustomed to travel across the

globe were suddenly immersed in a new social experiment where their basic rights to circulate freely were radically altered by the governments. The pandemic is changing human relationships, reciprocities and emotions and of course the ways of making sociology; so to speak, different social maladies already existent in the late capitalism – far from being resolved- become more acute in the post COVID19 context. Sociologists should re-imagine the infrastructure of a new social world based on social distancing, lockdowns and indifference by the “Other”. In this vein, Korstanje and George (2020) called the attention to the shifts in the travel behavior as well as in the ways the alterity is imagined in Western civilization. The scientific expedition that inspired the rise of sociology and anthropology started from the needs of “being there” to study the natives. The “Other”, for better or worse, was an object of curiosity which should be subordinated to the scientific gaze. In the days after 9/11, the “Other” is seen as an undesired guest, a potential enemy who looms to attack anytime and anywhere. In the post 9/11 days, anyone could be a potential terrorist while just after COVID19 all us are potential (terrorists) carriers of a lethal disease. Without any doubt, the world is experiencing a feudalization process where the national borders are in constant tension and negotiation but far from being a foundational event, COVID19 closes a process initiated after 9/11. In that process, the *Non-Western “Other”* is suspected to be a future enemy, neglected and exiled through the scrutiny of modern surveillance. In a nutshell, authors hold the polemic thesis that Western hospitality is dying by the introduction of a fear culture to govern the workforce (Korstanje and George 2020). In consonance with this, Geoffrey Pleyers (2020) acknowledges that the pandemic affirms the authority emanating from the classic nation-states in detriment of the global forces. Having said this, political scientists deal with the risks the world witnesses the emergence of populist leaders who foster nationalist discourse. As he eloquently notes, while the nations closed their borders, citizens looked inside their countries in quest of security and protection. As a result of this, international institutions titter in the brink of collapse. The consequences of COVID19 entail various geopolitical disputes accompanied by authoritarian guidelines for protection. Everything is allowed in the state of exception. Last but not least, social psychologists Lee Monaghan (2020) continues the discussion left by Scambler who coins the term *fractured society* to explain the inter-class (group) social conflict or tensions -in this case- generated because of COVID19. Departing from Klein’s concept *disaster capitalism*, Monaghan argues convincingly that COVID19 finally corroded the basis of human solidarity that was previously affected by the neoliberal agenda, in so doing, some social maladies that characterized liberal society abruptly surfaced.

This book, as stated, combines different theories, and conceptual frameworks giving fresh insights into the effects of COVID19 in modern society. If this represents the end or a re-start of capitalism only God knows, but what is insure is that the pandemic fractures human relations as never before paving the ways for the emergence of a new society based on the Spectacle of death. The “Other’s death” becomes mainly a factor of cultural entertainment for the global audience worldwide (Tumarkin 2005; Howie 2012; Korstanje 2016; 2018).

HOW TO READ THIS BOOK

Chapters organized in the present editorial collection can be read separately but they are integrated into a common-thread argument: the consequences of the pandemic in the different micro-sociological spheres of daily life. As remarked, the invited authors who are experts in their fields have no English as their native tongue. The main goal of this book aims to describe how COVID19 confronts with the Anglo-Saxon cosmology of the world. In so doing, the lens of authors plays a leading role to reconstruct the foundations to new critical sociology in ever-changing capitalism.

As the previous backdrop, the foreword elegantly, which is written by Freddy Timmermann-Lopez, interrogates furtherly the role played by *anger* in the constitution of the neoliberal agenda. Per his viewpoint, neoliberalism started with Allende's coup and the access of Augusto Pinochet to the presidency of Chile in 1975. Politically speaking, the climate of fear imposed by Pinochet not only paved the ways for the political disinterest but also facilitated the worker union dismantling. The recent protest and social discontent that destabilizes Piñera's administration comes from a belated retaliation resulted from decades of oppression. The private property which was the quintessential feature of the neoliberal order is now under attack. The recent virus outbreak (COVID19) activates old-fashioned (authoritarian) practices and dispositions such as the curfew or, army-force patrolling originally characteristic of Pinochet's Regime.

In the second chapter, Adrian Scribano discusses the interplay of hunger and the sociology of bodies (emotions) in the context of COVID19. He focuses his analysis on the pre-pandemic situation in Argentina which associates to a much deeper market stagnation, unemployment and perpetual economic crisis. Scribano holds the thesis that – far from being part of the solution, NGOs, the state and the market are allies who have disposed of the citizens' bodies to manage a climate of scarcity and exploitation. The struggle for containing the virus propagation alludes to a *bellicose metaphor*, the war against a virus!

Primavera Fisogni, in the third chapter, brings some reflections on the doctrine of living with the enemy in, which was originally forged by counter-terrorism experts. His chapter dissects the problem of West to understand the "Alterity", as a potential enemy – like the virus- living within. Her reasoning comes from the model friend-enemy in Carl Schmitt who has molded modern politics. As she puts it, the immunization makes the enemy (the virus) and the host adversaries. In this respect, any process of immunization disciplines the virus keeping it under the human control.

In this vein, Pedro Lisdero and Marion Fonrouge alert on the durable effects of the pandemic in society. To the problem of the internal enemy debated in an earlier chapter, this fourth one adds a more than innovating insight, the big data models and the digital platforms oriented to scrutinize daily social interaction.

These researchers find that the same technology used to follow up the traceability of messages, discussions revolving around COVID19 paradoxically commoditizes its users.

In the fifth chapter, Irina Burak and Tatiana Razumova expose the study case of the Russian Federation. From different angles, they review the negative effects of COVID19 in the Russian Federation. The COVID19 teaches us three sad realities, some people simply die (when their conditions aggravate), some lose their jobs and others may panic. The government adopted not only restrictive measures but also launched to bail out citizens and

private companies. The digital technology allowed social distancing as well as the home office in the entire federation. Resiliency will occupy a central position in the economic recovery of the Russian Federation.

In the sixth chapter, Fabio la Rocca explores the archetype of the urban landscapes (the city) in the context of social distancing. As he eloquently notes, the face of the city has been radically transformed by the restrictive measures adopted by Western states. The city, which historically was a site of connection, now becomes in a space of eradication. He coins the term *the desert city* to symbolize the days of lockdown in different in Europe. It is safe to say that the extension of the interior in our apartments was exteriorized beyond the window to recreate a social manifestation of tribal reciprocity during the COVID19. While forcefully constrained to stay safer at home, lay-citizens get out balconies to interact with “the Other”.

Angelica de Sena, in the seventh chapter, shows the grim future of La Matanza, one of the poorest and largest regions of Buenos Aires Metropolitan area. When President Alberto Fernandez decided to impose the lockdown it generated devastating effects for citizens who witnessed how the economy plummeted. She conducts some online surveys to describe the emotions of La Matanza’s dwellers. The obtained outcomes reveal that fear, and anxiety followed by boredom and worry are the main axes of what consulted people normally feel as long as the COVID19.

In the eighth chapter, Aldana Boragnio proffers a more than interesting diagnosis about COVID19 and the needs to be safe at home. For those who are forced to stay at home, the act of eating becomes a practice of the private domain. As she remarks, eating seems to be a social practice that reproduces the body while framing habits and customs as well as countless social sensibilities. The global pandemic not only alters diets but food practices in different ways. The chapter aims at describing the sensibilities of eating in the post-pandemic days while laying the foundations towards a new understanding of commensality, and the rite of the banquet.

The last chapter -on the ink of Adrian Scribano and Jorge Duperre- draws a comparison between COVID-19 and the Spanish Flu, a virus that whipped humanity in the former century. Authors use the term *present, mediated and cherished death* to explain the disposition of audiences to the spectacle of death, packaged and sold by the mass media. The pandemic suspended and radically changed all funerary rites, stripping out the veil of death from its sainthood. The act of dying accompanied or alone -exiled like Oedipus-, which is the core of the tragedy, seems to be one of the controversial themes this chapter deals with.

CONCLUSION

One of the problems of COVID19 remains with the fact that we know nothing respecting how this game ends. The chapters lumped together in this volume study the durable effects of COVID19 in different fields of private or public life. Basically, far from being a turning point, this pandemic seems to affirm the material inequalities and social maladies proper of capitalism which ranges from digital exploitation, to labor precarization or the introduction of a fear culture as a form of cultural entertainment. What is equally important, our travel behavior and customs changed in the same way how the foreign tourists are treated. Asian tourists not only are feared but discriminated as potential carriers of COVID19. The national

or inter-estate borders have been re-drawn in view of a new politics where the “Other” is the enemy – if not the terrorist- (Korstanje 2017). Whatever the case may be, the social distancing as well as the lockdown, recreates the conditions to the rise of new geopolitical disputes, chauvinist discourses, or long-dormant sentiment of separatism. Probably the global economy sets the pace to a more feudalized world where “the Other” becomes in an *undesired guest*. This process does not begin with the pandemic, but with 9/11 and the War on Terror. The virus, so to speak, closes the doors of an epoch I has dubbed as the *End of hospitality*, at least as we know it.

²Center for Research on Consumption, Sensitivities and Creativity (CICSEC),
University of Palermo, Argentina

ABSTRACT

Since government actions at all levels began in relation to the COVID-19 pandemic in Argentina, the State, the market and NGOs have been targeted at the poorest and most impoverished sectors of the country. Based on the analysis and interpretation of various records of the mass media and official documents, this article systematizes various difficulties around hunger, with the aim of opening a critical discussion on them from the perspective of sociologies of bodies/emotions. The expository strategy will be as follows: a) the theoretical starting point of the connection between hunger, the body and emotions is synthesized, b) the situation of poverty and pre-pandemic hunger in Argentina is outlined, c) some of the multiple emotions of the intervention are characterized and d) some interpretations of the interventions characterized are presented.

Keywords: hunger, social interventions, body, emotions

INTRODUCTION

Natural cataclysms, environmental catastrophes, wars, epidemics and pandemics have a common social phenomenon: hunger. Every society, by establishing food production procedures, satiety criteria and the practices of feeling associated with them, somehow establishes a politics of hunger. The political economy associated with capitalism, at least in

the last 400 years, set out to be a scientific regulation of scarcity as a “natural phenomenon”, generating a system of resource allocation based on unilateral accumulation and a social dispute of systemic adaptation. The state, the market and NGOs are part of the aforementioned processes of managing the scarcity associated with food and hunger. The declaration of social emergency and compulsory isolation immediately impacted the productive structure, labour management and consumption, causing the informality, precariousness and organizational disorganization existing in the country to emerge. Thus, since government actions at all levels began about the COVID-19 pandemic in Argentina, the State, the market and NGOs have made interventions aimed at the poorest and most impoverished sectors of the country. In this context, the present article tries to systematize various interventions around hunger, so as to open a critical discussion about them from the perspective of the sociology of bodies/emotions.

The research strategy and the material that serves as the basis for the analysis and interpretation come from three types of sources: a) records of the mass media and social networks, b) official documents and c) secondary data of other investigations that are being carried out in the Research Centre to which the authors of the article belong. The expository strategy that we have chosen is the following: a) the theoretical starting point of the connection between hunger, the body and emotions are synthesized, b) the situation of poverty and pre-pandemic hunger in the country is outlined, c) some of the emotions that characterize the multiple practices of intervention are outlined, and d) some interpretations are offered about the interventions characterized. The article tries to elaborate a critique of some practices, beyond their legitimacy, of being the product of existing needs, of enjoying political consensus, and of having the character of unavoidable actions to lessen the impact of the crisis. The militarization of the poorest sectors, the persistence of charitable models and the spectacularization of aid, today exacerbated pornographically, must be understood as the reproduction of a social structure configured several decades ago. We end up remembering the immense possibility that the emergency offers as a springboard for non-dependent social practices.

HUNGER, BODY AND EMOTION

Hunger is a social phenomenon that impacts the body. People need to feed to maintain the minimum state of reproduction of the organic processes that constitute what is called the body. The human person seen from a biological perspective is a complex interrelation between the volume of nutrients ingested, the energy expended to obtain them, and the quantum social energies available to manage these two components.

Hunger is a phenomenon of great variability that has various nuances: there is no single modality of hunger. Among the main types of hunger that can be identified in a diet, we find the following three: a) acute hunger, which is an intermittent phenomenon, with periodic but not continuous exacerbations and restitution; b) chronic hunger, of persistent and prolonged action, at the same time, that it can be qualitative or quantitative hunger - or both - depending on whether it refers to a diet with insufficient protein and vitamins or with insufficient calories; and finally, c) hidden hunger, which refers to malnutrition based on the lack of essential micronutrients for the biological, psychological and social development of people

(De Castro, 1962). The three types of hunger coexist worldwide, locating themselves to a greater or lesser extent in some countries and spreading differentially across the social strata. Today, hidden hunger is found in both industrialized and poorer countries; in the former due to excess consumption, and in the latter due to the decrease or absence of certain foods, to which chronic hunger and acute hunger are added as part of the global reality. This points to hunger as a primarily social fact since “hidden hunger today constitutes the most typical form of human-made hunger” (De Castro, 1962, p.54). But what is relevant about hidden hunger or malnutrition is not only the lack of nutrients but its extension over time and the consequences it generates, since hunger will not only have consequences on the bodies of people who experience it. It will also impact their offspring and thus the entire process of social structuring. Taking this characterization elaborated by De Castro and placing it in the context of the body, we find a conceptualization proposal around hunger from a vision of the sociology of bodies/emotions that emphasizes their relational character. So, individual hunger refers to the “lack of nutrients” experienced by the individual body at the biological level (socially understood). It refers to the absence of nutrients (in a broad sense) for the reproduction of that body. It is enacted at the level of the relations between individuals, social organizations, and the environment. Subjective hunger affects the “auto-reflexivity of the self”, i.e., it links the consequences of “identity” order, in the cognitive sphere which are related to hunger. It is enacted in the field of the relations of the human being with himself and its consequences in the embodied self-image of the subjects. Social hunger has an impact on the social presentation of the subject” (Scribano and Eynard, 2011, p.67).

Thus, we understand that individual hunger refers to the relationship between the human being and the environment, and subjective hunger refers to the relationship of the human being, while social hunger articulates the other two planes in connection with a life lived in a society. At the same time, these distinctions of hunger are connected with the distinctions of the body; therefore, hunger will affect the bodies on their individual, subjective and social¹ planes due to the unequal distribution of energy and nutrients, jeopardizing the corporeal existence as well as the possibility and power of action (Boragnio, 2018).

Bodies exist in connection with the environment from the processes that occur in the interaction between the brain, the central nervous system, nutrients and energies. Specifically, the concept ‘body energy’ refers to the direct relationship between the body and nutrients as a result of the exchange of physiological systems and biological processes that allow the durability of systemic functioning. This brings us closer to understanding the direct relationship that occurs between nutrients and the possibilities of action since social energy arises from this relationship, which “is based on body energy and refers to its distribution processes as a substrate of the conditions of movement and action. The power to plan, execute and resolve the consequences of the agents’ actions constitutes the social energy that they have” (Scribano and De Sena, 2016, p.116).

While body energy is directly linked to nutrients, without nutrients there will be nobody energy, so the greater the nutritional deficiency, the less the possibility of action. At the same time, “social energies are closely related to bodily energies, since the greater the nutritional deficiency, the greater the probability of structuring a set of weak human relationships”

¹ The individual body refers to phylogenetic logic, to the articulation between the organic and the environment; the subjective body is configured by self-reflection, in the sense of “I” as a centre of gravity through which multiple subjectivities are woven and passed, and the social body that is (in principle) the social made body. See Scribano, 2007; Scribano, 2005.

(Scribano and De Sena, 2016, p.116). Therefore, the possibility and power to plan and execute the action will be conditioned by the availability of energy and, thus, by the possibility of access to food. For this reason, it must be taken into account that the availability of food resources alters the quantities and the energy qualities that each individual has at their disposal, allowing these bodies to reproduce and be socially available. Thus, hunger will configure in the bodies small potentialities of the possible states of life of the subjects as social agents. Meanwhile, unequal distribution and appropriation of energy and nutrition affect the corporal energies and, therefore, the social energies. This defines hunger as a central experience of life, as it is structuring of emotions and sensibilities. Hunger highlights the intersections and networks between bodies/emotions due to their socially constructed character, while the direct relationship between energies and nutrients establishes limits and socio-biological spaces from which it is possible to observe how the individual body is the result of policies of bodies and policies of emotions, and its consequences that organize the reproduction of bodies and their availability.

POVERTY AND HUNGER IN PRE-PANDEMIC ARGENTINA

Hunger is always there. In Argentina, since the 1970s, poverty has continued to manifest itself as a problem of great magnitude and associated with it is the reproduction of forms of hunger. In the last quarter of the 20th century, there were global transformations that gave shape to what is known as the “new social question”, the sociabilities and experiences of poverty and hunger being a fundamental part of the politics of sensibilities across the century. In Latin America and the Caribbean, the problems related to the resources necessary for the reproduction of life implied an approach and strategies for the regulation of conflict and social consensus. For the first decades of the 21st century, new poverty assistance interventions were required that would reach levels of great massiveness. For the year 2017, the number of people living in poverty reached 184 million, approximately 30.2% of the region’s population, of which 62 million were in extreme poverty –10.2% of the population–, the highest percentage since 2008 (CEPAL, 2019).

In Argentina, poverty did not develop in a very different way. Poverty levels have skyrocketed since the early 1980s, with increases marked by economic crises, and it impacted between 20% and 35% of the population according to the period measured. At the same time, except for the 2001 political-economic crisis, poverty levels always found a new ceiling, higher than the previous measurement (De Sena, 2020). The latest data from the National Institute of Statistics and Censuses (INDEC) referring to 31 urban agglomerates, involving a population of 28,022,735 people,² indicate that, for the second half of 2019, the percentage of households below the poverty line (LP) reached 25.9%, which represents 35.5% of the population. Within this set, 8% of people (5.7% of households) can be distinguished below the indigence line (LI)³ (INDEC, 2020).

² The total population of Argentina estimated for 2020 is 45,376,763 people.

³ This refers to the fact that below the poverty line is 2,423,562 households, that is, 9,936,711 people, of which 2,236,739 people are indigent. These data are constructed from the Permanent Household Survey, referring to 31 urban agglomerates. https://www.indec.gob.ar/uploads/informesdeprensa/eph_pobreza_02_19SEFE752E31.pdf

Along with the historical journey that can be made through poverty data, data on social food policies must be added as ways of responding, regulating, normative, normalizing and mitigating conflict (Grassi, 2003; De Sena, 2011). Since the 1970s, the availability of food worldwide has been increasing. And since 1985 full availability of food was reached worldwide. This means that, statistically, with the current world food production, all the inhabitants of the world could obtain 2,700 Kilocalories (Kcal) daily⁴ (Aguirre, 2010). However, for that year, the Food and Agriculture Organization of the United Nations (FAO) registered 875 million people as malnourished (Aguirre, 2015). Currently, the figure rises to 820 million people who suffer from chronic hunger and reaches almost 2 billion if we talk about those who suffer from hidden hunger and malnutrition (FAO, 2019). In this way, it is exposed that hunger is not a problem of availability or production, but rather a problem of access to food. In Argentina, in mid-1984, during the government of Raúl Alfonsín, the National Food Program (PAN)⁵ was launched, which consisted of delivering food bags to families that presented some nutritional risk, popularly known as “box PAN”. This was conceived as a two-year emergency program, but President Alfonsín kept it running until the end of his term. In the beginning, the PAN was estined for 907,360 families; in 1985, it was extended to 1,487,118, but three years later, boxes were being distributed to 1,506,470 families⁶ (Sordini, 2018).

Subsequent governments, to date, have continued with food policy, but PAN was the first strictly food-related government program⁷ and is considered the tracer thread of Argentine food programs, due to its scope, coverage and mode of implementation (Sordini, 2018). In this context, the “social question” was present, taking the form of hunger experienced by those social sectors that remained stuck in the place of the structural failure of the current accumulation regime. As De Sena maintains, “the processes of inequality and expulsion generated in the structuring of a society based on the commodification of life cause conflictive breaks that must be systematically remedied” (2014, p.155), and the taking of food is one of the main breaks that were configured from the 1980s.

Beginning in the 1990s, the Conditional Cash Transfer Programs (CCTP) began to be implemented as a modality of attention to poverty. These programs underwent rapid expansion and attained a massive reach, but at the same time that they were incorporated, those referring to food were not neglected, therefore the beginning of the overlap of programs can be observed. From 1990 to date, a variety of national food programs have been established. Among those that are still in force are the ProOrchards program, which has been operating since 1990, the Program for the Promotion of the Welfare of the Elderly (PPB), since 1992, and the National Plan for Food Security (PNSA), which was reconverted in 2003. To these, we can add the National Care Prices Program, which began in 2014.⁸

⁴ The amount of Kcal changed over time.

⁵ ‘PAN’ is the acronym in Spanish.

⁶ A separate issue is the number of boxes that were delivered, since although the number of families that were part of the PAN increased, the boxes did not always increase in the same proportion. Thus, we found that, if in 1987 16,488,304 boxes were delivered to 1,341,078 families, in 1988, 14,950,678 boxes were delivered for a little more than 165,000 extra families (Aguirre, 1990).

⁷ In 1936, Law 12,341, “Palacios Law”, was enacted, which was regulated in 1938. It attempted a “response from the State to the health, food and nutrition problems of the maternal and child population of Argentina, in a situation of poverty” (Abeya, 2016, p.591), but it was only put into national operation in 1952 delivering milk under the name of Maternal and Child Plan, which continues to this day.

⁸ To this, it is necessary to add the Universal Assignment per Child (UAC) that was implemented in 2003 and the Pregnancy Allowance for Social Protection, since 2011. Both programs enter the conceptualization of PTCI

At present, the current food policy at the national level is called Plan Argentina contra el Hambre and “it is supported by the strengthening of the actions carried out by the National Program for Food and Nutrition Security. It implies the promotion and strengthening of Access to the Basic Market Basket.” (Argentina, n/d-b). Within this program, there is the Alimentar Card, which is a pre-loaded card that allows you to buy food –except for alcoholic beverages– and is intended for mothers or fathers with sons and daughters up to 6 years of age who receive the UAC, for pregnant women who from 3 months after pregnancy receive the Pregnancy Allowance, and people with disabilities who receive the Universal Assignment per Child. This program is “a comprehensive food supplement policy” (Anses.gob, n/d). As of March 11, 2020, 1,100,000 cards were delivered and “it is anticipated to deliver more than 1,500,000 cards, which will reach more than 2,800,000 recipients” (Argentina.gob.ar, 2020, March 16).

Hunger as a topic was of concern to various governments as well as serving as a political flag –and it is again today. This brief overview shows that, since the implementation of the PAN, the target population did not overcome the need for help to respond to their food needs. Thus, the applied programs, far from solving the food problem, denote a plot that sustained over time not only the dependence of the recipients on them and the reproduction of inequalities but also an increase in the number of people who are in need of state interventions. In this way, we can observe that, in Argentina, for a long time, there have been food policies that attest with their mere presence that hunger is always in any of the aforementioned modalities, thus configuring the pre-pandemic context of a structural problem: the uneven distribution of nutrients. In what follows we will describe the special association between militarization, policing, spectacularization and the commodification of aid that actions against hunger imply in the days of the COVID-19 Pandemic.

HUNGER INTERVENTIONS AND POLICIES

In the context of the generalized crisis produced by the planetary extension of the COVID-19 pandemic, the Argentine National State designed a battery of state actions to avoid its untimely and deadly eruption. Since the beginning of the Preventive and Compulsory Isolation decreed by the National Government on March 20, a reinforcement of state assistance to the poorest families in the Metropolitan Area of Buenos Aires and the country in general began. The Army and the Churches are involved in a variety of them, at the same time as solidarity actions by companies were added, which had as a point of maximum visibility the holding of a televised event to raise funds for aid to the Red Cross.

Army, Food and Conflict

A basic feature of state interventions in this time of pandemic is the use of the war metaphor to describe the set of actions configured to lessen their impact. The President of the Nation in his speech announcing the Isolation maintained:

since they grant money through transfer in exchange for some conditionalities. For more detail, see De Sena, 2011; Dettano, 2019.

"I thank you too, you are part of those who are exempt from the rule of staying at home, those who work in the media, journalists, I thank you very much for being here, I please ask that you help me to inform well, because as I told you last time, *one is fighting against an invisible enemy, who gets into our room, and one cannot detect it, but one has two fights: they are the fight against the pandemic and the fight that is constantly going on against psychosis*, those feeling that everything is very serious, that everything is irreparable and that nothing can be done." (Words from the President, 2020, March 20)

In this generalized and normalized context of the war metaphor, the participation of the Armed Forces is something very foreseeable as a material "reinforcement" of this war due to the politics of sensibilities launched by an invisible external enemy: biologically and psychologically invisible. In Argentina, the Army in the streets implies updating phantoms of the set of policies of the sensibilities associated with dictatorships. Although the presence and reconversion of the Gendarmerie to policing tasks has indeed become daily since at least 2004, the decision to "use" the army is a practice that fortunately has not been naturalized. The Argentine Army is currently forming part of the emergency plan about the pandemic. On its website it specifies:

"In compliance with the directives issued by the national executive power, the Argentine Army enlists and prepares for the maintenance of the necessary means so that the Operational Command of the Joint Chiefs of Staff of the Armed Forces uses the necessary military resources (mainly health and logistics) to support the community in this Emergency caused by the COVID 19 Pandemic." (Argentina.gob.ar, 2020, March 27)

At the beginning of this fulfilment of tasks, they were involved with the logistical service of food distribution and food assistance. For example, in La Matanza,⁹ Army personnel are deployed to carry out food distribution tasks –rice stew, noodle stew or lentil stew– in three-hour shifts per day, in which 24,000 food rations are distributed daily (Ayerdi, April 5, 2020). The explanation for the need to call upon the army to carry out this task focuses on the fact that "a food delivery operation of this magnitude is unprecedented" (Fuego Simondet, April 5, 2020) and that the army has the necessary resources such as kitchen equipment, industrial-size cooktops and the logistics necessary for the distribution.

These tasks gain greater visibility based on observing the geographical location map of military personnel, whose activities are detailed and range from assembling tents and beds for patient isolation, water supply, food processing and distribution, to satellite telecommunications support, air patrol and reconnaissance flights; these activities are concentrated in the east, northeast, west, northwest and the Metropolitan Area of Buenos Aires (Argentina.gob.ar, n/d-a).

But, the participation of the Army in the social tasks of the pandemic must be related to the diversity of "anti-looting" plans that are carried out mainly in the Metropolitan Area of Buenos Aires by the Security Forces. In this sense, an Emergency Operations Centre was created, made up of the areas of Security, Social Development and Health (Ayerdi, April 5, 2020) to work together on an emergency plan linked to avoiding social conflict. This further complicates the Army's presence with the phantom structure of the looting associated with the 2001 crisis and the set of social responses to various food, poverty and work crises. In the recent history of Argentina, it is possible to verify, in the last four decades, the repetition of the crisis, looting and repression connection.

⁹ It is the largest and most populous party in the Metropolitan area of Buenos Aires and in the province of Buenos Aires. It has a population of 1,775,816 inhabitants according to the 2010 census.

"In this sense, the records of 'Nueva Mayoría' (2013) indicate that, for the period 1989 and 2013, 3,356 cases of looting have taken place, place in the context of the "outbreak of hyperinflation" (1989) some 676 cases; in the "outbreak of convertibility" (2001) 875 cases, 10 to which 151 lootings occurred in the first weeks of 2002 are added. In the subsequent period, looting has a low frequency (2003: 14 cases; 2008: 9 cases; 2009: 5 cases; 2010: 26 cases; 2011: 11 cases) until December 2012. That month, the looting began in Bariloche, spreading to several provinces, reaching a relative peak of 228 cases. In 2013, the phenomenon acquired a greater magnitude, accounting for a total of 1,266 cases (surpassing previous peaks)." (Scribano and Lisdero 2017, p. 338)

On April 15, the President of the Nation, Alberto Fernández, gave a speech at the Gendarmería School where he not only referred to the health/economy dichotomy but also announced the tripling of the Gendarmería's participation as a force that will control "compliance with quarantine" in La Matanza (Coronavirus en Argentina..., April 15, 2020). As of that day, the Gendarmerie is in charge of carrying out security care and quarantine control tasks in the largest municipality in the country (Fernando..., April 15, 2020). Given this, the communal chief ended the event saying that:

"Today is a happy day for La Matanza. The President came to fulfil our request for more than four years: that the National Gendarmerie patrol the streets of La Matanza again. Today we are responding to a complaint from all our neighbours. That an institution so loved by our citizens returns to our streets generates a lot of tranquillity, because the Gendarmerie came to take care of the best capital we have, our people. (...) That the National Gendarmerie returns in these difficult times that we are living in Argentina and the world with the coronavirus pandemic, it also gives great peace to all the neighbours." (Fernando ..., April 15, 2020)

To this must be added that at the beginning of the period of Preventive and Compulsory Isolation there was an intense wave of control and "discipline" for those who broke the isolation, since "between March 21 and 31, only the national security forces had 644,009 people notified and/or controlled on public roads, of whom 19,939 were declared infringers" (Colectivo Editorial Crisis, April 1, 2020).

At the same time, in the future, there is already talk of a joint action initiative between state entities, social organizations, universities and the Army for the reconstruction of areas affected by the pandemic (Acción Social..., April 16, 2020).

To the deployment of the army in relation to food assistance has been added the aid of the national government. According to the journalistic note published on April 5 in the newspaper Perfil, the national government went from assisting eight million people to assisting 11 million. At the same time, "more than 300 million pesos was allocated to the municipalities for the purchase of food and there was an increase of 50% in the amount of aid to 3,000 soup kitchens that the ministry assists" (Ayerdi, April 5 2020). For their part, the municipal mayors signed agreements with supermarket chains, some of whom collaborate with the preparation of the food bags that the municipality distributes.

The National Administration indicates that the need for assistance increased as workers in the informal economy, who until now had no link with the ministry of social development, joined the demand for food. Additionally, there is an increase in attendance at soup kitchens, which look for a way to continue operating at a time when the demand from neighbours increases day by day. For this, they mainly make pot meals that allow the portions to be "stretched" to increase the quantity. Later, some soup kitchens organized a "delivery picketers" to bring food to the elderly in the neighbourhood. Likewise, the news highlights that, despite the changes and the efforts at organization, there was a lack of food (Colectivo Editorial Crisis, April 1, 2020) and that individual actions add to the attempts to feed

neighbours and people in the neighbourhood (Cassini, April 18, 2020). This scene prepares us for the next section where it is possible to capture the unfolding of the commitment of all the Churches to addressing hunger in the context of COVID-19.

Churches and Charities

The history of the so-called “social question” has involved from its inception various forms of charity and philanthropy; the consequences of the pandemic bring with it new scenes of an elaborate narrative between good intentions, guilt, and manipulation.¹⁰ For their part, the Churches organized an initiative called “#SeamosUno”, in which various religious, Catholic, Christian and Jewish associations participate. They, in turn, solicited participation in the form of donations from associations and chambers of commerce. On its website, where “who we are” is defined, we see the slogan:

“Together with CIAS-Compañía de Jesús, CARITAS, Banco de Alimentos, the Council of Evangelical Pastors of CABA, AMIA, ACIERA-Alianza Cristiana de Iglesias Evangelistas de la República Argentina and other business and social organizations, we have decided to launch the project #SeamosUno with to raise funds to be used to buy food and cleaning units, which will be distributed to those who need it most. The initiative implies an exhaustive control in the processes of collection, acquisition of products, assembly and control of boxes, delivery of the same. The project is being jointly audited by Deloitte, EY, KPMG and PWC to ensure the transparency of the process.” (Seamosuno, 2020)

It seeks to raise funds and donations in kind that allow the elaboration and distribution of food boxes (Ini, April 4, 2020). By April 17, 100,000 boxes with 15 kg of non-perishable food each had been distributed,¹¹ and funds are being raised to complete 400,000 more boxes, but the objective of the action is to deliver one million boxes of food to four million people, “especially to the informal sectors that do not have the habitual assistance of the State” (Naishtat, April 19, 2020).

In the conformation of these boxes, you can find donations from large national and some international companies, which provide products, boxes and logistics. The goal is to deliver 1,000,000 boxes. As we can see, the one million became a social fantasy: represented with the imaginary of multiplicity, of the exaggerated and the uncountable quantity of opulence.

The Jesuit priest Rodrigo Zarazaga, the main promoter of this practice, stated in an interview: “The people of the villages do not want chaos, but hunger leads to despair and their persistence can end in situations that we do not want; for this reason, this campaign seeks above all that no one goes hungry and that we stop in the face of the abyss” (Rubin, April 7, 2020). It is clear, once again, that the objective of conflict management and suppression of inequality lies in the conditions that preceded and pre-existed the pandemic. The other side of these commitments is the presence of the Army and its relationship with the Churches present

¹⁰ We want to make clear, once again, that our criticism of being structural and sociological implies not making the mistake of adopting the ecological fallacy, that is attributing to each individual what in fact refers to the level of the collective and systemic.

¹¹ The seamosuno page states: “Each box contains different food and hygiene products to cover the essential needs of a family for a week. Food products cover up to 56 food servings. Next, we give you the details of the products included: Rice/dry noodles - 4 kilos, Flour - 2 kilos, Tomato puree - 2 units, Tin cans - 2 units, Dried lentils or beans - 1 kg, Long-life milk - 3 litres, Mince can - 4 units, Canned fruits - 2 units, Toilet soap - 2 units, Detergent - 1 unit (300 cm3)” (Seamosuno, 2020).

in the poorest areas of the Metropolitan Area of Buenos Aires. In the GPS television program hosted by the journalist Rolando Graña, on A24,¹² on April 24, 2020, a segment titled: “Soup kitchens in the Metropolitan Area of Buenos Aires are seen. If there is no mass, there is a table”. In this segment, the host of the program visits one of the Chapels of Padre Pepe¹³ in the Barrio Independencia of the Partido de San Martín,¹⁴ showing how, due to the prohibition of religious ceremonies and the food emergency, the chapel has become a community feeding centre. In the scene, lasting 1.36:33 minutes, you can see the host of the program showing how to eat where mass is commonly celebrated and showing the place to viewers, while saying: “[we can see that] the care of the Parish, the order... is in charge of army personnel...”,¹⁵ while at the same moment, the camera takes a shot of two uniformed men and women, standing in a military posture. The synthesis is more than clear, the two institutions that guarantee social and moral order together in an intervention against hunger, the questions that arise are more than obvious: How will the situation of citizen security be if the Army has to guarantee order? What will be the level of poverty if it is the Church that must complement/replace the functions of the municipal state? The first answer, also obvious, is that this is Argentina before, during and after the Pandemic. One more band in Moebius’s to which our investigation takes us here is the connection between dealing with hunger and the show.

Spectacle and Pandemic Sensibilities

The COVID-19 pandemic involves a contradictory set of modifications in sensitization policies on a planetary scale, and one of the most evident aspects is the acceleration of the spectacularization through the mass media and social networks. In Latin America, at least, every earthquake, volcano eruption, hurricane, torrential rain leaves bare what society only hides behind a pornographic acceptance: the existence of some structural absence.

With the “Teleton”,¹⁶ at the regional level, and with “A sun for children”¹⁷ in Argentina, as paradigmatic television programs of the spectacularization of humanism diminished in its form of “anonymous donation”, it constitutes one of the pillars of the systematic acceptance of the object of the collection: inequality about televised absence.

The centrality of the show is one of the fundamental components of global awareness policies:

“...the processes of crisis and metamorphosis of capitalism have been associated with staging and spectularity. From the Paris Fair of 1910, through the Hitlerian concentration camps, to NASA’s launches, capitalism has always shown its power through public spectacles. Today, in the Internet era and live broadcasts for billions of subjects, the spectacularization takes (and re-takes) other features to gain importance and centrality. All that is lived must be represented in public, massively transmitted and recognized/approved by “many”. Every day of spectacle implies the appearance of a “reality show”-spirituality... .” (Scribano 2017, p. ...)

¹⁷ https://es.wikipedia.org/wiki/Un_sol_para_los_chicos.

On April 5, the programme “United by Argentina” was broadcast, a television program organized at the request of the wife of President Alberto Fernández to the Argentine Red Cross to channel donations to acquire basic supplies for the pandemic: mouth cap, gel, respirators, etc. The program - which was broadcast in unison on all the broadcast channels and in which the collection of 88 million pesos was reached between donations and advertising guidelines (Trzenko and Fernández Cruz, April 5, 2020) - sought to “provide the opportunity Argentines to come together in the same voice of solidarity” (Unidos por Argentina [United for Argentina], n/d).

When closing the program (in a pre-recorded video of 3:56 minutes) Fabiola Yañez - first lady of the country - said “...*Thank you for being there ... I love you, love us, we love each other.*”

The television special lasted almost 6 hours, in which recognized figures from the show and local television made their appearance, taught viewers recipes to cook at home, showed activities that could be shared with the family at home, and doctors known to the public advised about how to prevent and control coronavirus. At the same time, tributes were offered to the security forces, accompanied by speeches and the language of war. Thus, there was talk of “an invisible enemy”, of a “silent war” and allusions were made to the Falklands War.¹⁸

Along with this special moment and demonstration of donation, it is also possible to find other initiatives by businessmen, unionists and officials around food and its distribution that are “made known” or that are directly part of the marketing of companies. An example is Orange Card, which targets its advertisements with the motivation “we can all do it together” and aims to donate 20,000,000 pesos.¹⁹ As another example, in Chubut a fishing vessel that had to make a transfer trip caught 40 tons of hake (with fishermen who carried out the work as solidarity cooperation, not charging wages) to “distribute it among the poorest sectors of three cities in the province of Chubut “ at Easter (Carpena, April 9, 2020).

All this has been complemented by numerous proposals for donations and contributions from a “solidarity of companies” of various kinds, amongst which stands out that of the “Group One Led”, the leading firm in advertising business on Led screens:

“With the focus on awareness, Miranda and his company decided to donate advertising space on their screens to help protect against the pandemic. How does it work? As he explained, it is a campaign that is projected free of charge on more than 60 screens located on public roads throughout the country where they transmit dynamic content in real-time that promote care and protection against COVID19 and that are part of the “Stay Home” campaign.” (Zanotti, April 8, 2020)

The need is to make the population and the newly connected advertising media known in a society where if you don’t see you don’t feel. Thus, shows, celebrities, companies, and advertising reconnect “as they know how to do it”: the best way to generate an impact is by creating sensibilities. Where there are no state resources, the spectacular sensibilities raised to serve as an appeal to dissolve institutional responsibility. Once again, Argentina’s everyday reality appears in exceptional times.

¹⁸ During those days, in various places on social networks, allusions were made to a historic and well-remembered program called “The 24 hours of the Falklands” which “... was a program broadcast in 1982 for 24 hours to raise funds for the men who were to fight the Falklands War. However, although the fate of the proceeds cannot be established, it is clear from the statements of its protagonists that it never reached its destination.” https://es.wikipedia.org/wiki/Las_24_horas_de_las_Malvinas.

HUNGER GAMES IN THE CONTEXT OF A PANDEMIC

In the movie “The Hunger Games”,²⁰ games with the same name are developed, which are a televised competition for the hungry to survive.

“The nation of Panem emerged from the ruins of what was once known as North America. 74 years ago, the 12 poverty-stricken districts in Panem revolted against the wealth that the Capitol controls. After its overwhelming victory, the Capitol devised “The Hunger Games.” Each year, each district must hold a raffle (known as the harvest) to choose a man and a woman (ages 12-18) to participate in “The Hunger Games,” a competition in the that each of the 24 participants (known as tributes) will fight to the death in a televised arena until only one is alive. However, this is simply an annual reminder to the twelve districts of their authority and as punishment for the rebellion made 74 years ago.”²¹

As in this film, the Argentine National State, in coordination with that of the Province of Buenos Aires, inaugurated an intervention based on the militarization of the struggle for survival. The “presence of the army” in the Metropolitan Area of Buenos Aires (and later throughout the country) and the results of containment are obvious: given the impossibility of quarantine by millions of people, the risk of social conflict increases and this leads to the pursuit of three goals: a) organize the population “on-the-street” (queues, clubs, neighbourhood centres, schools, etc.), b) reduce the risk of looting and c) control crime in the “assisted” areas.

These practices, beyond the obvious consequences for the risk of contagion, imply legitimization of the police and of the armed forces, the consolidation of the food dependency and the acceptance of the almost non-existent capacity of the Social Organizations which today occupy positions in the Ministry of Social Development among other state agencies.

The religions, with obvious and indisputable goodwill, reproduce a mechanism of direct assistance with the support of the technology of the 21st century - traceability of what is delivered - but with the charitable scheme of the 19th century where the other continues to be a passive agent and receiver. The articulation of different religious expressions, especially between the Christian and Catholic churches, guarantees the initiative a reticular procedure that efficiently links need and satisfaction, but with the limitation of the duration and contingency of such assistance.

The companies have initiated a set of interventions as we have narrated, but the “public-private television festival” is the one with the most massive consequences. Three elements should be highlighted: a) the open and massive television channels are the vehicles of the initiative, reproducing the political economy of current morality, conflating the logic of the show, donation and enjoyment; b) the reproduction of diminished humanism and the trivialization of the good; and c) the consecration of state failures in the acquisition of supplies necessary to face the health crisis.

To close the interpretation that we have been making, we want to point towards the recognition of two intervention devices on the survival of the poorest and hungry.

The s+c+c device (state+churches+companies) that was undoubtedly designed to “alleviate” the crisis, has an unintended consequence of its action and performative

²⁰ The Hunger Games is a science fiction, action and drama movie. Directed by Gary Ross and based on the best-selling novel of the same name by Suzanne Collins. It stars Jennifer Lawrence, Josh Hutcherson, Elizabeth Banks, Liam Hemsworth, and Woody Harrelson.

²¹ [https://es.wikipedia.org/wiki/Los_juegos_del_hambre_\(pel%C3%ADcula\)#Recepci%C3%B3n](https://es.wikipedia.org/wiki/Los_juegos_del_hambre_(pel%C3%ADcula)#Recepci%C3%B3n)

effectiveness: it clearly shows that Argentina was already in crisis. It shows that the depth of the crisis is such that there is nothing more appropriate than the word Emergency to describe it: the weak institutional fabric emerges. And the S+I+E (State + Intervention + Emotions) device, understood as an active equation in interventions on hunger, functions in terms of the policies of sensibilities that the construction of specific emotions provides in the context of the pandemic and food.

The diminished humanism that characterizes the aforementioned spectacularization is constituted by “a set of practices that operate as a mechanism for suturing differences and inequalities between classes. These practices are characterized, among other features, by inverting the place of the collective and the individual, erasing their differences; dilute social cooperation regimes, replaced by blaming fictions; leave the receiving subjects in an iterative situation as a grantee; replace state presence with private action; and re-inaugurate philanthropy and private charity as mechanisms for attention to deficiencies” (Scribano 2014, p. 81).

Beyond the analysis provided here, and further, on what emerges when the crisis deepens, beyond the politics of perversion (Scribano, 2015) and further than meanness and selfishness, it is possible to perceive hundreds of thousands of interstitial practices that speak of a different way of understanding what is happening. Precisely, the fact that millions of people around the world and in Argentina have grasped the “logic of what emerges” implies that there are other opportunities not to repeat the spectacular militarization of a diminished humanism that always leaves us in a state of dependency.

Chapter 492

THE ENEMY INSIDE

Primavera Fisogni*

La Provincia di Como, Italy

ABSTRACT

The global world has recently been under attack from a new enemy, whose microscopic shape shuttered every aspect of human life: health, relations, social and economic frames. The COVID-19 outbreak can be compared to a war, with relation to the number of victims made worldwide. Still unknown in its several biological aspects, Coronavirus is currently going to update the concept of enemy. As I intend to argue, the pandemic brought to the forefront the idea of *enemy as an insider which constantly interacts with the host*. The enemy can be attacked only assuming it, making it part of both the individual body and the social body. According to this perspective immunization cannot be seen in terms of an exemption but properly as an inclusion. My reasoning starts from a short account of the classic paradigm of friend/enemy sketched by Schmitt (1932) and developed by Vitale (1992) in order to show the novelty of the ‘enemy inside.’ Then I’ll take in consideration the processes that give rise to immunization, through the lens of General System Thinking (Urbani Ulivi, 2019) that better fit the purpose to explore such a complex topic. I’ll reach the conclusion that immunization makes the enemy (virus) and the host (the biological substratum) adversaries: this dynamic, by reducing the dangerous potential of enemy, puts it under control. Thus, any process of immunization can be interpreted as the making of a community, differently from Esposito’s theory (1998; 2001) of a sharp distinction between *immunitas* and *communitas* (immunity/community).

Keywords: coronavirus, enemy, conflict, immunization, immunity, community

* Corresponding Author’s Email: pfisogni@gmail.com.

UNDER ATTACK OF A VIRAL ENEMY¹

An epidemic plague initially focused on China, affected the world as never before in the last century. A short account of it is necessary before investigating the topic of the present paper. The Coronavirus Disease 19 (COVID-19) outbreak has brought about a radical turn of the social, economic, and cultural scenario since January 2020. The speed of the contagion has spread faster than the SARS epidemic rush in 2009 so that the Chinese Government decided to lock down Wuhan, the main town of the Hubei region. Although the report from China profiled a red alert from the very beginning of the epidemic emergency, it took time before the WHO (World Health Organization) declared that the epidemic outbreak was turning into a global pandemic. Face masks, gloves, special protection and careful attention to cleaning have become new social practices for everybody. After struggling against the viral attack, the world is aware that the war is far from over and a new enemy is taking the scene. The micro-organism that affects all social levels in a macroscopic way is a case study also for philosophy and political sciences because it updates, with the power of an earthquake, models and frames that, after the pandemic, seem worn and inadequate.

The Virus as an Enemy: Limits of the Discourse

Since the very beginning, the Coronavirus pandemic has been equated by the media to a “public enemy number one” (Boseley, 2020), whose potential could be easily compared with that of terrorism, as the director-general of the World Health Organization Tedros Adhanom Ghebreyesus warned (“Viruses can have more powerful consequences than any terrorist action”). The media coverage focused on military metaphors for sketching its profile, so that COVID-19 was said to be the “biggest challenge since Second World War” (Angela Merkel, *The Telegraph*, 2020), “the invisible enemy” (James McAvoy, *Daily Mail*, 2020) who “moves among us unseen” (*The Conversation*, 2020) in the “frontline” (*The Guardian*).

The microscopic bio-organism is a veritable enemy for life because it moves inside blood circulation and the respiratory system. Differently from a parasite, which can be taken together as a companion, the virus immediately shows its hostile intentions to the guest, through a huge attack to the very heart of the life in itself. What makes the situation more complicated for COVID-19 is that, in the majority of the cases, the virus does not show itself with the unfriendly consequences of its deadly potential. As always happens for the phenomena described through metaphors, the war against COVID-19 highlights the limits of any discourse and the urgent need to know what sort of enemy coronavirus is. The conceptual difficulty that coronavirus designates does not only depend on the still unknown biological dynamics of the virus; as I intend to argue in my paper, the pandemic updated the notion of the enemy by introducing a substantial novelty within the traditional debate about this topic. More precisely, the pandemic provides us with a better understanding of how the concept of enemy works within the frame of the immunization processes, as will be explained in the following paragraphs.

Deeply interwoven with interdisciplinary implications, the term enemy is generally referred to an individual of whom to beware because of its dangerous potential. The notion of

¹ This investigation is dedicated to Mario Antonio Clerici, with whom I discussed the main argumentations of the present work.

the enemy makes primarily refers to the opposite of friend, as someone we can trust and deal with. On the psychological ground, an enemy is a subject who gives rise to a cluster of bad feelings – fear, anxiety, anguish, terror – which are expected to destabilize a single individual (Gosio, 2020) or a community (Ceri and Lorini, 2019; Schlee, 2010). In his pioneering investigation on the concept of the enemy, the *Der Begriff des Politischen* (1932), Schmitt assumes that it is the intensity of the degree of association/dissociation to decide who is ‘friend’ (*Freund*) or ‘enemy’ (*Feind*) in political terms.

A very complex word, the enemy is rooted in the Latin word *inimicus*, formed by the negative element *in-*; hence, an enemy is “what a friend is not.” In Slavic languages, where the enemy is *neprijatelj*, this conceptual framework is still relevant, different from the Latin and German languages, as noted by Vitale (1992). Schmitt shed light on the ‘private enemy,’ a concept that differs from the ‘public enemy’ (*Feind*) and the ‘other/stranger’ (*Fremde*). The best reference for framing a ‘private enemy’ can be found in the Latin word *hostis* [*host*], an ambiguous term where two semantic areas are deeply intertwined: the one belonging to the guest as someone who is accepted, included, recognized and another one dealing with the enemy, who gives rise to hostile behaviors against the community (Plumper and Neumayer, 2010).

What makes an enemy a ‘private foe’? The conceptual field of *hostis* embraces the main idea, among others, which deals with the domestic frame in which both the guest and the host are dwelling. It may be concluded that the ambiguity that entails the term is strictly related to the kind of relationship existing between two subjects, both within a commonplace. Despite the rough description, this passage is highly relevant in the perspective of this current investigation, because it could be applied to the immunization process, in order to prove that COVID-19 brought in to act a private enemy, a contemporary *hostis* who currently inhabits the global fears.

What Kind of Enemy? The Identification of the Foe

Only the identification of the enemy makes the hostile individual a target against whom to act, with good chances of stopping it. As Aho underlines, groups socially construct enemies according to five steps, moving from the naming of the foe, the most crucial rank of the operation followed by legitimation, mythmaking, sedimentation and ritual (Aho, 2010). Profiling the enemy in the process, often questioned (Lyon, 2003, 2007), through which the ‘public enemy’ is set up. It is proper at this point of the process that the traditional distinction between 1) enemy and 2) friend makes sense. When the foe is detachable, community glues together against it and empowers itself (Schlee, 2010). This dynamic, on which the classical idea of war is based, has been completely surpassed in the last two decades by global conflicts and especially by the war on terrorism, where the difficulty to focus on a visible enemy gave rise to the new categories of the ‘terrorists from next door’ and the ‘lone wolves’ (Fisogni, 2014, 2019).

In the struggle against a pandemic, as in any conflict, the need to focus on the public foe is necessary to delete it. When scientific investigations proved unable to forge biochemical weapons to flatten it, superstition and rage easily took their place. During the bubonic plague that struck Milan, in Italy, in 1630, the plague spreaders (the *untori*) were hunted and executed. These persons, as Italian leading novelist Alessandro Manzoni reported in the *Infamous Column* (*La storia della Colonna infame*, 1843), were innocent but reputed guilty by

the crowd. The necessity of identifying them as ‘public enemies’ by the social community and the execution that occurred on the public square, was endorsed by the Milanese judges although it was illegal (Ciacca, 1985). As this episode witnesses, the wish to shape the enemy goes along with the necessity to bring a scapegoat onto the stage.

According to the victimization hypothesis theorized by Girard (1982), even if an innocent is going to be executed, the act is expected to solve a social crisis through exceptional measures that surpass any prescribed laws.

The COVID-19 pandemic updated this frame more softly. The single scapegoat, which is identified and then destroyed by the enemy, has been replaced by the collective ritual of wearing a face mask. Behind a behaviour due to the collective wealth, a powerful metaphorical operation for targeting the enemy can be noticed. In a pandemic, everyone can be seen as a potential enemy and a virus spreader. At the same time, anybody may be a victim of the virus itself. The two grounds of the phenomenon interfere, interact and are faced up together. As it happens with someone guilty for having committed a crime, in the lockdown as well as in the quarantine people have been imprisoned at home for weeks and have to abdicate several freedoms guaranteed by civil laws (Campi, 2020). We all were protected, we all had to guard against the enemy from the next door.

In the bubonic plague of 1630 ordinary justice was left outside tribunals, as Manzoni underlined, for allowing the public rage to compensate the frustration of coping with an epidemic that took nearly 50% of Milan’s population. Although the constitutional laws of democratic countries consider several freedoms as unquestionable, social or pandemic emergencies, as happened within the Coronavirus outbreak, it nevertheless tends to inhibit several personal rights for the sake of public health. The lockdown experienced worldwide made it visible on a global scale. We are now in the condition to move into a further stage that will allow us to highlight the main novelty of the concept of enemy provided by the COVID-19. As I intend to argue, the pandemic brought on the scene the idea of the enemy as an insider. The enemy can be attacked by only assuming it, making it part of both the individual body and the social body. Hence, the topic of immunization becomes very key to reshaping this issue.

Immunization as the Integration between Host and Enemy

Immunization is a recurrent topic within the Coronavirus pandemic. In the biomedical language, it is the process that brings immunity or protection to the living organism. This kind of response, which is the specific reaction of the immune system to a pathogen, allows the system to generate an immunological memory that keeps the individual safe from the risk of getting infected by the same virus or bacteria. The second relevant process related to the immune system is its innate response to pathogenic attacks, by the immediate mobilization of cells against infection.

The origin of immunology as a science dates the inoculation of cowpox introduced by Jenner against smallpox in 1796; however, it should be ascribed to Pasteur the idea of inducing immunity throughout attenuated microorganism (vaccination) in 1880.

Mainly regarded as “a complex mechanism of integration of microbes into the cell community of the host” (Igea, 2015: 55), the term immunity is frequently applied to several different fields. During the last two decades, the concept expanded from the biological domain into political philosophy giving rise to a new field of investigations, especially in

Italy where Esposito theorized (1998, 2001) immunity as the paradigm for globalization. In his analysis, immunity and community share the idea of an obligation, a *munus* in Latin, on which a couple of terms is semantically rooted. The immune person is someone who got free from the obligation and, for it, has temporary or placed himself outside the community. Although immunity is expected to safeguard the individual/social body, Esposito argues that it is at the same time something that inhibits the development of a community and, over a certain degree, it can destroy social cohesion.

As Igea argued from the biological perspective, there is a gap between “what ‘immunity’ etymologically means and what the term implies today” (2015: 55), however, the conceptual core of the word maintained certain stability throughout its semantic changes: it refers to an exemption/freedom of duties for some individuals with which other subjects have to comply. It is in fact in virtue of this particular condition, within the social/political discourse, that the social *community often looks at the immune as an outsider*, someone about whom to be cautious for his being out, free from a collective *munus*. Within the frame of the COVID-19 pandemic, an immune individual is someone free from the infectious disease, nevertheless, he remains involved at large with the hostile agent for having hosted it. The infection has changed his biological structure and made of him the ‘other,’ that’s to say a subject that stands apart from the community and can be included only with a watchful approach.

At this point in the paper, a question arises. *Why does a community tend to isolate immune subjects?* They felt as potentially hostile as if they were still in relation with the pathogenic agent. I call this condition ‘the enemy inside.’ In the next paragraph, I’ll seek to get deeper into this insight through the lens of General System Thinking.

Processes of Immunization: from Exemption to Integration

In this section, I aim to clarify the concept of the ‘enemy inside,’ as a result of the immunization process. This conceptual frame cannot be understood according to linear thinking because, as already seen in Esposito’s theory, immunity and community stand apart as separate poles. Therefore, I suggest changing the interpretative paradigm, by investigating this topic through the lens of General System Thinking (Urbani Ulivi, 2019; Minati and Pessa, 2019).

According to GST, living phenomena are considered in term of open systems; it means that they are not mere aggregations or sums of parts, but primarily dynamic units, to which belong qualities that depend upon many interactions and processes, internal or external to the system, the continuous exchange with the environment that gives rise to systemic properties or II type systemic properties. According to this philosophical perspective, immunization cannot be considered first and foremost an isolated phenomenon which stands outside a community. Living systems, as human individuals or societies, are coherent structures engaged in “a continual (extended) critical transition” (Minati, 2019: 16). This instability is due to the degree of organization that is “maintained by the integration/regulation activities of the organism that is by its global coherent structure.”

It follows that immunization is a twofold shaped phenomenon: it is a dynamic system involved in a permanent critical transition. If we come back to Esposito’s dualistic frame (1998, 2001), it becomes clearer why the immune subject cannot be fully integrated by the community. An immune is someone who experienced a radical change in the very intimate texture of the system. Thus, he can change his mind, he can assume behaviors and beliefs that

are different from the ones shared by the social group and, for it, they may destabilize society in reason of his ‘permanent critical transition.’ *Communitas* of non-immune people, on the contrary, maintains its properties stable over time, “including evolutionary patterns” (Minati, 2019: 16). A community tends to glue together its components, leaving outside whatever can destabilize it, within an incessant demand of self-protection. However, being involved in several processes, a community needs preventive immunization from any thrust that might undermine its coherence.

The contradiction that *immunitas/communitas* paradigm brings to surface can be easily solved, within the frame of General System Thinking, by taking in account the conflict between 1) transition and 2) coherence of change and stability, two aspects that are deeply intertwined in open systems that pertain to life’s domain.

At this point in the discussion, we can take another step into the discussion.

Immune people and non-immune individuals can be equated to systems with different dynamics, which constantly interact. They show different degrees of reactivity to the thrust of the environment. Immunization belongs to the domain of dissipative structures, referring to the coexistence of change and stability (Prigogine, 1967, 1981, 1999). As Minati notes, non-equilibrium conditions allow the emergence of ordered structure. Furthermore, the stability of dissipative structures “is due to their ability to transfer a large amount of entropy to their environment” (Minati, 2019: 33). Concerning a community system, where stability is provided primarily by coherence, an immunization system constantly transfers energy outside itself, it is more dynamic and for it, less predictable. At this point, we can better grasp why immune subjects are perceived as destabilizing although immunity is a necessary step for protecting a social group: their access to the community brings into it the sphere of what is *out* and can be hostile *in* a community because it is not known.

In the next paragraph, we’ll focus on these two poles.

In and Out, Two Conflicting Poles?

The terms *in* and *out*, which take a relevant part in the friend/enemy discourse also belongs to the immunization process and, at large, to the dissipative systems, to which also immunization belongs. This consideration is highly relevant in order to move from the biological frame into the political environment. Before discussing this passage, I briefly recall that a *community* is the typical in-group society, where the individual share common values, laws, habits, cultures and way of life. The notion of humanity itself “can be understood as a set of concepts related by family resemblances” (M. Bilewicz, A. Bilewicz, 2012: 341). If commonalities are expected to paste together a society, they need to be constantly reinforced by differences which belong to the ‘out’ environment. The out-group is perceived as stranger, different, hostile. Qualities that properly belong to the semantic field of ‘enemy,’ as also Schmitt underlined in *Der Begriff des Politischen*, by assuming that *Fremde*” was primarily the other, the stranger” (Vitale, 1992: 92, translation is mine). The divide between the two poles is sharp in social dynamics, however in terms of open system processes, the two poles are closely involved in relation, in a continually in-out-in-out interaction.

In the dissipative systems – where change and stability coexist as seen before – the environment is a perfect copy of the system because of the interacting fluxes that move from both. It is the case, for example, of human brain dynamics, where environment is generally called ‘the double’ of the brain (Vitiello, 2010: 115). The entrance/exit streams have to

balance to allow the stability of their interrelation. If the problem of enemy is considered from this perspective through the lens of General System Thinking, the terms *in/out* can hardly be separated. They are activities whose interaction is needed for allowing coherence. What makes it difficult for the community to include immunity and the related phenomena within its borders is the possibility to cope with processes that may bring about changes in the social environment. From the GST perspective, this is the particular kind of interactions that belong to any dissipative system. A community tends to prefer compatibility to irregularity or unpredictability. When the interaction is provided by dissipative systems like immunization, where the poles *in/out* are in constant relation, the possibilities that new emergences emerge is highly predictable. In terms of social dynamics, deep changes are expected to affect the community. Immunization, being an emergence as “a continuous, irregular, and unpredictable process of acquisition of non-equivalent (...) properties” gives rise to II type systemic properties.

This passage focuses on the possibility that immunization can eventually allow the community to become steadier through internal changes. What the dynamics previously explored highlight a profile which seems suspended between safety and danger, the conflict between friend and enemy.

Let's turn to our topic: are *in/out* conflicting poles?

An immune individual cannot be considered an enemy anymore but it is not fully a friend, it is a non-friend. It is a concept that is attested in the Slavic languages, as Vitale underlined (1992) and Schmitt intuitively grasped in *Der Begriff des Politischen*. As the semantic roots from Indo-European domain highlight, an enemy originally refers to someone who stands outside the peaceful community, which is ruled by divine laws. Differently from the enemy, who is permanently in conflict with the State, a non-enemy plays a constructive role for the community because, as Vitale assumes, political friendship can be built only in presence of him (Vitale, 1992: 90). While the enemy questions the existence of the community, the non-friend presents a variety of shades, within a psychological frame that enhances the processes of dialogue/understanding. As Vitale notes, the “non-friend should be seen as an eminently psychological relation” (1992: 93). Nevertheless, Schmitt had already grasped in his seminal work – as Portinaro argues (1992) – that legacy rooted on a common offspring were too feeble for grounding a valuable theory of political friendship.

I'm now able to formulate my argument and to set my argumentation on more secure ground. At this point in the paper, we should move forward, into the very heart of the immunization process, which will surprisingly reveal a community-like environment more than an exemption place. This premise will bring about a change in the notion of an enemy.

Immunization: a Process of Integration. How the Enemy Builds Up Friend

As Vitale assumes, “the category of friend derives from a psychological process of auto-ascription that is possible only in virtue of the counter opposition” to the enemy (1992: 105, translation is mine). It follows that “it is impossible to elaborate a theory of the political friend (...) that prescind from the opposition to the enemy.” Thus, a conflict always goes along with the need of sharing a common environment, at least from a psychological perspective. I argue that immunization is very key for highlighting this interconnection. By bringing inside the enemy, immunization clarifies the process that turns hostility into peaceful coexistence, or a permanent transition from conflict to regulation from the systemic outlook.

This dynamic maintains a coherent level of organization because of its systemic novelty: it is an emergence, or a II type systemic property, which does not belong to the enemy (out), nor to the community of friends (in) but always need to be fed by both systems. We are at the very heart of the problem investigated in this paper.

It can be expressed by the question: *how does the category of 'friend' be built by 'the enemy inside'?*

The first step is to highlight on *coherence*, which is the process that supports any emergence. In the biological frame of living entities, for instance, health is the state of maximum coherence; on the contrary, any disease gives rise to the isolation of a part, or function, or property of the whole system from the systemic unitary and general coherence. The virus, as a pathogenic agent, by infiltrating within the bodily system as an enemy, disconnects the previous harmonic balance of the bodily system. The loss of coherence clarifies why a process of emergence may be extinguished as the consequence of an inconsistent organization. At the same time, coherence also supports the unitary and integrated response of the system to disturbances/perturbations, avoiding isolation or the independent organization of some parts or functions. Both the innate and the adaptive response of the immune system work as such against the infection.

If the individual 1) is strong enough to react to the virus or 2) a vaccine has been injected into his body, the biological response against the pathogenic agent will not simply destroy it; it will give rise to a reaction that reconnects – in a completely new and different way – functions and properties previously being offended. This leading reaction, within a frame where structural incompleteness is a condition of the process, makes an emergence to be possible. Thus, the enemy, as a process of dissipation and rupture, is expected to provide a stronger coherence in the system.

An enemy could be regarded as a change enabler, an activator of emergence.

We can refer once again to biology, focusing on the parasite/host interaction. The host is commonly perceived as an organism that harbors another living entity inside its specific environment. Worth noting that the Latin word *hostis* resonates in the word *host* with its inner ambiguity of either 1) a guest and 2) a hostile attacker. This set of considerations provides a valuable premise to assume that the process of immunization, where a “friend” of the organism (the host) is targeted by an “enemy” (the pathogen, the virus) is a peculiar battlefield where each attack becomes an integration, in an incessant dynamic that keeps the organism safe or the reverse. From this point of view, immunity cannot be the opposite of a community because integration is a process that lies at the very heart of both. The notion of ‘enemy inside’ inhabits this environment.

At this point in the discussion, it would be easier to understand why this integration/connection between an *enemy* and a *friend* (of the community) might be highly relevant for understanding how an enemy is expected to lose its destructive potential, turning into a non-friend. As Vitale noted, political friendship can be built through the enemy and only in virtue of this immunization process. If we look at the two poles (enemy/friend) as separate entities that never match or interact, we’ll never be able to solve the contradiction. On the contrary, as argued before, they are regarded in terms of open systems that interact. The immune system proves that pathogen/host interactions do not only exist but are part of the process. Criticism can be made, through a question: *how to move from the biology to the classic conflict dynamics?* I’ll reply by providing an argument that has been already briefly sketched by philosopher Derrida (1995) and now seems highly valuable to strengthen the idea

of the ‘enemy inside’ as a *trait d’union* between enemy and friend. It recalls, on the political discourse, what has been previously understood in the biological and systemic fields.

In his analysis of Schmitt’s *Der Begriff des Politischen*, Derrida assumed that the enemy is an individual who is entirely shaped by the conflict, according to what also Vitale underlined (1992). It is right there in the battlefield, within the crucial space of the frontline, that the foe becomes fully identifiable; however, while the *polemos* builds up the enemy’s identity, it also seems to do the reverse, forging a sort of commonality between the two parts in the battlefield. In Derrida’s view, this face-to-face condition is expected to delete any difference between enemy and friend. The making of *adversaries* is really what happens in virtue of the *polemos*, which brings together, as Derrida states “those two are opposed and it provides a historic figure for this *polemos* that brings enemies together as though they were conjoined in the extreme proximity of face-to-face” (p. 37). In the conflict, in other words, ‘enemy’ is no more a term that stands in opposition to ‘friend’; it turns into an adversary who *participates* in strengthening its identity as well as the one of the other adversaries who are now sharing the conflict experience. On the other hand, this frame highlights on how crucial it is “to construct a distance between soldiers and their enemies” in order “to be able to kill adversaries” (Grossman, 1995).

If we come back to immunization as a conflict that takes place within of the biological system of the individual against the virus, we understand that the enemy (the virus) is defeated when the body assumes some properties of the *enemy* itself, turning into the *adversary* of the virus. Hence, in the immunization battle, the enemy, which is “existentially something different and alien” (Schmitt, 1996: 27) makes its double: the adversary.

CONCLUSION

This paper was intended to focus on the novelty that COVID-19 brought into the discourse about the concept of enemy. As we noticed at the beginning, the metaphors of war are deeply related to the pandemic: what I sought to do, in my investigation, is to turn the limits in understanding the phenomenon into a fruitful resource to understand its opaque ground. I noticed that the concept of the enemy cannot be easily separated from the one of a friend, since the classic Schmitt’s theory (1932) to Vitale’s investigations on the non-friend, which introduced a more complex understanding of Schmitt traditional divide between (public) enemy, friend and private enemy.

Secondarily, I argued that the very idea of enemy, in the COVID-19 pandemic, should be about the immunization process, that’s to say with the battlefield where the conflict against the pathogen coronavirus is performed. Immunity, the condition provided by immunization, is a term that turned from biology into politics and philosophy, in opposition to community. As for the couple enemy/friend, the distinction between these two poles gives rise to a contradiction (Esposito, 1998; 2001). However, if we look at the COVID-19 outbreak scenario, we realize that – at least on the biological ground - immunity is not in conflict with the community. Thus, the idea of an ‘enemy inside’ which could be a relevant part of the process of immunization, kept on being shaped by the discussion.

A change of paradigm was due, to reach some valuable results. Far from being a universal key for grasping complexity, the systemic perspective might be seen as a toolkit to

solve some – not all – traditional philosophical problems, as the enemy/friend dual pole. According to the GST I could argue that immunization, which is a II type systemic property could be regarded as an integration more than an exemption. This idea, gained from the dynamics of dissipative systems can be found also in the biological dynamics of the pathogen/host interactions.

One of the most relevant insights that come from this passage is about the in/out poles, whose interaction is as relevant as their opposition. A further step was to assume that immunization, too, is a process of integration which may be highly relevant to clarify how the enemy builds up the friend, as Schmitt had already shown in his seminal essay (1932) but never developed, and Vitale (1992) integrated with an enlarged perspective on political psychology.

Finally, I noted that conflict is necessary to transform an enemy into an adversary: this is the very basis for making political friendship possible. Pacts can be done between adversaries, because they are a peer in the *polemos*, in virtue of being face-to-face on the frontline. Immunization is not simply the destruction of the foe; it is a more complex process that turns two parts in conflict into adversaries: thus, the enemy does not disappear completely; it turns into an adversary who can be controlled and can enhance the capacity of the reaction of the immune subject. Immunization is the phase in which the enemy is defeated according to a pact with him. Since the virus is an enemy outside the biological body the war cannot be won. What does this phenomenon say to the traditional debate about the concept of the enemy? It highlights the impossibility of making a sharp separation between enemy and friend, as if they were two separated poles, without any communication or any mutual exchange. Through the lens of the General System Thinking, friend and enemy are open systems that interact, especially in the immunization process, a veritable conflict where the two subjects/systems become adversaries. The adversary emerges as a II type systemic property that does not belong to any previous system but cannot be shaped without their mutual interactions.

²University of Palermo, Buenos Aires, Argentina

ABSTRACT

On March 11, 2019, the World Health Organization declared the status of a pandemic for the rapid expansion of COVID-19. In a short period of time, the daily lives of billions of people around the world would never be the same: the successive strategies that were adopted in different countries implied significant changes in most of the subjects' daily experiences, from the way of working to the family relationship itself. Most of the situations of interactions in the context of the pandemic are carried out in virtual contexts, and specifically through social networks. Thus, COVID-19 is imposed as a recurring "topic of discussion": WhatsApp groups, Facebook, etc. are filled with messages and discussions about it. Thinking in terms of social research, it is possible to imagine a Big Data strategy to analyze the traceability of messages, and to map the density of the circulation of information. However, it is also possible to ask ourselves some questions that seek the qualitative meanings of the practice of receiving and re-sending messages related to the subject, while taking into account its relationship with their form. In this direction, the objective of this chapter is to analyze the emotions linked to the interactions in social networks associated with COVID-19. To do this, we applied a self-administered survey to 307 respondents in 17 European countries, selected using the snowball sampling technique between March 17th and April 18th, where we inquired about how people feel when they receive/send information related to the pandemic. Given the multiple possible interpretations, we are interested in linking some discussions around digital labor, that is, the ability of social networks to market to an audience. This means emphasizing one of the ways these media have, in the framework of the renewed

and massive situations of digital interaction, of capturing people's energies and transforming them into merchandise (Fuchs, 2014). The analysis focuses on the fact that what is commercialized is the willingness to be part of a group that receives messages, so it is not enough to just know the quantifiable dimension of the action of forwarding, but also what is at stake is the relationship between the objective field and the willingness of the subjects to be part of these audiences. Therefore, beyond the re-production of the practice (whether it is re-sent or not re-sent), we are interested here in exploring how the qualitative sense that agents give to it could be associated with policies of digital sensibilities (Scribano and Lisdero, 2019). That is, perceptions framed in specific regimes of sensibilities that allow connecting bodily geometries with grammars of action (Scribano, 2017) that have a specific support and content in the digital field. This allows us to advance in the description of "platform sensibilities" as a sign of the ongoing social structuration processes.

INTRODUCTION

On March 11th, 2019, the World Health Organization declared the status of a pandemic for the rapid expansion of COVID-19. In a short period of time, the daily lives of billions of people around the world would never be the same: the successive strategies that were adopted in different countries implied significant changes in most of the subjects' daily experiences, from the way of working to the family relationship itself.

Most of the situations of interactions in the context of the pandemic are carried out in virtual contexts, and specifically through social networks. Thus, COVID-19 is imposed as a recurring "topic of discussion": WhatsApp groups, Facebook, etc. they filled with messages and discussions about it. Thinking in terms of social research, it is possible to imagine a Big Data strategy to analyze the traceability of messages, and to map the density of the circulation of information. However, it is also possible to ask ourselves some questions that seek the qualitative meanings of the practice of receiving and re-sending messages related to the subject, while taking into account its relationship with their form. In this direction, the objective of this chapter is to analyze the emotions linked to the interactions in social networks associated with COVID-19. To do this, we applied a self-administered survey to 307 respondents in 17 European countries, selected using the snowball sampling technique between March 17th and April 18th, where we asked about how people feel when they receive/send information related to the pandemic. Given the multiple possible interpretations, we are interested in linking some discussions around digital labor, that is, the ability of social networks to commodify an audience (Fuchs, 2014). This means emphasizing one of the ways these media have, in the framework of the renewed and massive situations of digital interaction, of capturing people's energies and transforming them into a commodity. The analysis focuses on the fact that what is commercialized is the willingness to be part of a group that receives messages, so it is not enough to just know the quantifiable dimension of the action of forwarding, but also what is at stake is the relationship between the objective field and the willingness of the subjects to be part of these audiences. Therefore, beyond the re-production of the practice (whether it is re-sent or not re-sent), we are interested here in exploring how the qualitative sense that agents give to it could be associated with policies of digital sensibilities (Scribano and Lisdero, 2019). That is, perceptions framed in specific regimes of sensibilities that allow connecting bodily geometries with grammars of action

(Scribano, 2017) that have a specific support and content in the digital field. This allows us to advance in the description of “platform sensibilities” as a sign of the ongoing social structuration processes.

THE EMOTIONAL COMMODIFICATION OF THE AUDIENCE

Given the breadth of the problem linked to the relationship between emotions and pandemic, we have focused on the specificity of digital labor, and its links with the processes of commodification enabled in digital media. To do so, we will rely on the analysis of empirical data built from the "Covid and Emotions" Survey (CIES). This study was undertaken using a non-probabilistic, exploratory design, where the snowball technique was used for the construction of the sample. A self-administered form was applied, elaborated from the "google form" tool, which contains a series of closed and open questions related to the relationship between emotions and COVID-19 (in addition to other general information). Thus, a total of 307 responses were collected between March 17th and April 18th. Most of the responses are concentrated in Italy (152 cases, or 49.5%), Spain (62 cases, or 20.2%), France (33 cases, or 10.6%), United Kingdom (11 cases, 3.5%), Portugal (11 cases, 3.5%), and Russia (10 cases, 3.2%). Other countries from which responses were received are Belgium, Austria, Germany, Greece, Ireland, Sweden, Hungary, Finland, Luxembourg, Czech Republic and the Netherlands. The age of the respondents ranges from 17 to 73 years, grouped as follows: 23.1% are between 17 and 25 years; 32.2% are between 26 and 35 years; 24.8% are between 36 and 45 years; 13% are between 46 and 55 years; 4.2% are between 56 and 65 years, and 2.6% are 66 years of age or older (about 57% of the sample is between 26 and 46 years). Sixty-four percent (64%) of the respondents are women, while 33.2% are men (1.9% responded "Prefer not to say"). With respect to educational level, 89% of the sample has completed university studies. The main occupations recorded are: "Professional, technical and related worker" (28.3%), "Student" (27.7%), "Government/public sector" (14%), "Administrative, managerial" (9.4%), "Unemployed/looking for work" (4.6%), "Other service worker" (3.6%), "Sales" (3.3%), "Home-based worker/subcontractor" (2.6%), and "Housework" (1.6%).

In this chapter we will focus on two questions: "Have you re-sent information related to COVID-19 through WhatsApp, We-Chat, Facebook, Twitter, Instagram or other social networks?"; and "Why?." Next, we advance making explicit an analytical proposal, and presenting some preliminary results that make it possible to draw some interpretative lines regarding the proposed objectives.

Digital Labor, Audience Commodification, and Emotional Work: Contributions from Sociology of Sensibilities

Many of the interaction situations in the context of the pandemic are carried out through digital media, and specifically through social networks. Within this framework, COVID-19, as well as all the "news" that were installed about it, was imposed as a "topic of discussion":

WhatsApp groups, Facebook, Twitter, Instagram, TikTok, and in general the most popular social networks were invaded by messages and discussions about it.

A first interesting question could be "what does these media, which we summarize here as Social Networks (WhatsApp, Facebook, Twitter, etc.) have in common?" In what sense does the capacity of digital media to "commodify an audience" expand from the practices involved in the use of these social networks? Recovering the analysis of Dallas Smythes (1977) on the notion of audience commodity, Fuchs (2014) observes:

"(...) the rise of user-generated content, free access social networking platforms and other free access platforms that yield profit by online advertisement—a development subsumed under categories such as Web 2.0, social software and social networking sites—the web seems to come close to accumulation strategies employed by capital on traditional mass media like TV or radio. Users who upload photos and other images, write wall postings and comments, send mail to their contacts, accumulate friends or browse other profiles on Facebook constitute an audience commodity that is sold to advertisers. The difference between the audience commodity on traditional mass media and on the Internet is that in the latter case the users are also content producers, there is user-generated content and the users engage in permanent creative activity, communication, community building and content production. That the users are more active on the Internet than in the reception of TV or radio content is due to the decentralized structure of the Internet that allows many-to-many communication. Because of the permanent activity of the recipients and their status as prosumers, we can say that in the case of corporate social media the audience commodity is an Internet prosumer commodity. (Fuchs 2010b)" (100)

Within the framework of a sociology of sensibilities¹, the discussion raised at the crossroads between digital labor² and the commodification of audiences opens up the possibility of asking ourselves about the bodily energies that support these renewed processes of capitalist accumulation. For this we need to incorporate the notion of emotional work:

¹ Schematically, we could say that the aforementioned Sociology of Sensibilities is inscribed in a particular perspective (Scribano, 2017; Scribano and Lisdero, 2019) that recovers the centrality of the body/emotions in social theory in order to understand the current processes of social structuration. The idea of body seeks to stress an individual body (bio-physical substrate), a subjective body and a social body. Emotions can be seen as the puzzle that comes as an action and effect of feeling or sensation: these situate in the states of feeling the world that allow the organization of perceptions associated with socially constructed forms of sensations. From this we understand "bodily energy" as the result of the exchange of physiological systems and biological processes associated with the durability of the individual body, but also as the (insubstantial) substratum of the processes of value creation in societies. The work in Western capitalist history can be historicized in an important dimension of its expression, starting from the constant re-inventions of the corporal energies, in consonance with the metabolic mechanisms linked to the accumulation regimes. Within this framework of general understanding, we think that the consequences and central effects of the relationships between Society 4.0, digital labor and the social structuration process are the changes in the politics of sensibilities, understood as the set of cognitive-affective social practices tending to the production, management and reproduction of horizons of action, disposition and cognition. (Scribano, 2017, Scribano and Lisdero, 2019).

² Three analytical nodes are differentiated in the available research on the notion of digital labour: (a) the discussion about the objects of expropriation in digital processes, highlighting the differential place occupied by the body and knowledge within the framework of a renewed discussion about the theory of value (Fuchs 2014; Fumagalli, 2015; Dyer-Witheford 2015; Morini and Fumagalli 2010; Huws 2016; Andrejevic 2012; Fisher 2012; Fisher and Fuchs 2015; Heam 2010; Vercellone 2006); (b) discussions about work processes and their material supports (time/space coordination of productive interactions), in the framework of which the notions of "Prosumption" (Ritzer and Jurgenson 2010), or "Playbour/Gamebour" (Arwid 2015), "free labour" (Newfoundland 2013; Kosnik 2013) "unpaid labour" (Fuchs, 2014), and cooperative/collaborative work (Meil and Kirov, 2017) are discussed. The idea of a "platform capitalism" (Cingolani, 2016) characterized by the growing place of the so-called "sharing economy" (Irani 2015; Cingolani 2016) emerges here. (c) Finally, a third group of researches deals with the constitution of the subjects that work, highlighting intensification, dependence (global), feminization and neo-taylorization (Huws, 2016), precariousness (Dyer-Witheford, 2015) and heterogeneity (types of organization, environments, contractual relations) (Fuchs and Sandoval, 2015). The perspective proposed here starting from the discussion about the body/emotions linked to digital labour, and seeks to establish the mediations between the vitality of bodies and emotions as an object of exploitation.

early on, A. Hirschfeld (1983) analyzed flight attendants and insurance salesmen by taking as a focus of reflection the connections between the emotions produced in work and the processes of value production. The author proposes that there is an institutionalization of the emotional order of the work environment on the intimate sphere, where the management of affects in the labor world begins to possess a certain predetermined and coercive character. Emotions are no longer elaborated from a discreet and personal management, and become instead a work that is marketed to the public. Precisely his study shows that many workers now do not simply sell their physical strength, nor their knowledge or rational capacity, but they also place their emotions on the market. Taking up Hirschfeld's idea, we are interested here in asking about the expansion and mutation of this trend, specifically in the context of the expansion of digital labor.

It would be impossible in this space to expand on the various responses that have been offered regarding this relationship (digital labor - emotional work): we ourselves have provided some analytical keys in order to make explicit the possible contributions of a sociology of sensibilities in the complexities of the notion of digital labor (Scribano and Lisdero, 2019). In this direction, the centrality of emotional work in our societies could be connected to the observations that Fuchs makes about the processes of value creation in digital labor assumed in social networks. In this regard, Fuchs notes:

“Whereas wage labour is coerced by the threat of physical violence (the threat is death because of the lack of being able to purchase and consume goods), audience labour is coerced by ideological violence (the threat is to have fewer social contacts because of missing information from the media and missing communication capacities that are needed for sustaining social relations). (...) If for example people stop using Facebook and social networking sites, they may miss certain social contact opportunities. They can refuse to become a Facebook worker, just like an employee can refuse to work for a wage, but they may as a consequence suffer social disadvantages in society. Commercial media coerce individuals to use them.” (2014: 90-91)

“(...) Marx argues that for being considered a productive worker, “it is no longer necessary for the individual himself to put his hand to the object; it is sufficient for him to be an organ of the collective labourer, and to perform any one of its subordinate functions” (ibid., 643–644). This means that productive labour understood this way implies that a worker who contributes to a “social product” that is controlled by a capitalist and is the “joint product of a collective labourer” (ibid., 643) is an exploited worker, no matter if s/he receives a wage for it or not. S/he is part of a collective or social worker. (...) “(2014: 109)

“Social media users are double objects of commodification: they are commodities themselves and through this commodification their consciousness becomes, while online, permanently exposed to commodity logic in the form of advertisements. Most online time is advertising time “(2014: 101)

In the quoted fragments, we highlight three elements: 1. the extortion associated with the “ideological violence” to which the “digital workers” are subjected is experienced from the “fewer social contacts” and “the suffering social disadvantages,” which puts the “body” at the center of the scene as the origin of social relations, and as the privileged “platform” where the social processes of production begin and end; 2. the productivity of connection, as well as the exploitation associated with the mutations of the value chain, needs to be explained from a collective body - a “living organ” that as the engine of life is captured in its productivity from a sociability that requires a particular “way of being”; and 3. precisely this is what we could read behind the idea of “commodification of consciousness,” a subsidiary of the digital moment of the “consciousness Industry” (Hans Magnus Enzensberger, in Fuchs 2014). Accommodating the collective body of digital workers to the demands of the 4.0 “consciousness industry” implies a self-production that we could associate with “emotional work.” The key to this association is to think about embodied consciousnesses: emotions

connect the sensitive and biographical expression of bodies with the social trends from which these bodies are marked. Contrary to the notions that consecrate the body-mind division, our proposal lies in connecting digital labor with emotional work to emphasize that affects are re-invented as "productive muscle." This has a differential characteristic in a world where social networks have colonized the internal planet: this "emotional muscle" cannot be thought of without the digital context. Thus, thinking about emotions in the context of social networks allows us to take a relational look at the "collective body" of digital workers as the (insubstantial) substratum of the processes of value creation and valorization from the affects that are commodified in/by social networks. We propose here to think about the commodification of affects as a necessary element to understand the "commodification of audience."

In order to operationalize this discussion, and advance in an analytical approach that allows us to put it in the context of some emerging empirical evidence, we will recover the two questions referred to in the survey on "Emotions and Covid-19." In this direction, we could think that the first question (Have you re-sent information related to "COVID-19" on social networks?) is an indicator of the processes of "commodification of audiences" in a double sense: in the first place it is an objective indicator of the potential of future communications, as a multiplier possibility to demarcate and build the audience (by amplifying interactions). Secondly, even when the subjects do not re-send the message, they are still not exempt from reproducing audience commodification, as long as they remain interacting in the digital medium, and therefore, building (possibly) data that are captured, processed and sold as commodities by the corporations that control the digital interactions. We will call this second dimension "limited re-production" of the audience, to differentiate it from the alluded to "extended re-production," although we must also clarify that the range of possibilities of digital relations should also include the possibility that the subjects can remove this logic from the commodity. However, we will not analyze this dimension here, since our objective is to explore the "emotional environment" that can be linked to the commodification of the audience.

It is not enough just to know whether or not the subjects re-sent messages: one may not have re-sent but even receiving it is part of a chain whose objective conditions of reproduction far exceed the calculation of individual behaviors. In other words, what is at stake is the relationship between the objective field and the willingness of the subjects to be part of those audiences. Therefore, beyond the re-production of the practice (whether or not to re-send), exploring the meaning that the agents imprint on it is more interesting from our perspective, inasmuch as in this set of dispositions they express the objective conditions of this chain of value production.

Thus, the information contained in the second question is important: "why did you decide to send/not send?." Since this is an open question, we chose to recategorize the answers received by registering them as an indicator of the "policies of sensibilities," that is, by differentiating in them (only for analytical purposes) the cognitive content from the affective one. The first dimension grouped the responses according to four emerging logics: 1. "Logic of Communication" - the meaning of the action is related to different motives aimed at facilitating communication, clarifying information, denouncing fake news, avoiding "noise" in communication, and so on e.g., "to inform people about fake news"; 2. "Logic of knowledge" - the sense of action is related to the search for intervention in the processes from which to approach the "truth" (about what is happening) e.g., "share knowledge"; 3. "Logic of

responsibility" - the sense of action emphasizes the consequences of individual actions aimed at the achievement of the "common good" e.g., "because I don't want to help spread fear"; and 4. "Logic of imitation" - the reason for action is to ensure a minimum degree of interaction without reflecting on the meaning of the action, imitation, or entertainment e.g., "to have a conversation."

The second dimension mentioned (affective) was reconstructed by identifying six groups of "feelings practices": 1. "Knowledge/awareness" - this includes feelings practices associated with the need to "become aware" (e.g., "because it's important for people who don't know what the problems are"); 2. "Trust" - sensations linked to trust/distrust with respect to people, institutions, etc. (e.g., "I'm not sure of its truth"); 3. Feeling useful/Care/Interest/Solidarity-Hope" - a set of feeling practices that, although they have certain peculiarities, all highlight the personal affective involvement in the consideration and possibility of action oriented towards an "other" (e.g., "I feel like adding some help for the society"); 4. "Love/friendship" - sensations where what is emphasized is the bond of love or friendship (e.g., "to inform my friend about some topic"); 5. "Fear/Anxiety" (e.g., "I'm against panic"); 6. "Entertainment": practices of feeling associated with the sensation of entertainment (e.g., "For sharing ... coronavirus jokes").

We would like to offer some clarifications here: the construction of categories for the dimensions mentioned was undertaken aiming at the greatest capacity for grouping them, fulfilling each one of the options the necessary characteristics of exhaustiveness and mutual exclusion. In this sense, the imputation of meaning in the re-coding process emphasized the identification of the cognitive logics and "feeling practices" predominant in the expressions made by the subjects in the form. The proposed categories constitute an analytical effort to reduce the complexity of meaning that these expressions embody.

Finally, before presenting some preliminary results from the analytical proposal presented, it would be relevant to say something more about our point of arrival, an issue that we could discuss based on the relationship between policies of sensibilities – the geometry of bodies and grammars of digital actions³. In other words, we would like to ask ourselves here in what sense the constructed information informs us about the perceptions that the subjects have about their practice (condensing and paradigmatic linked to networks and coronaviruses), and how those perceptions are framed in specific regimes of sensibilities that allow connecting geometries with possible digital grammars.

As a summary, the analytical proposal presented here could be summarized as follows (Figure 1):

Presentation of Data and Preliminary Readings

The study shows that a significant majority of people (71% of the respondents) resent messages linked to "COVID-19" through their social networks (Figure 2). If we take the reasons for these actions as a group between those who forwarded and those who did not forward, we find that:

³ The notion of the geometry of bodies refers us to the dispositions that "shape" society from particular coordinates of the social positioning of bodies. For its part, the idea of the "grammar of actions" allows us to access the common ways of giving meaning to social practices in-and-by-the bodies referred to (Scribano, 2004b).

Figure 1. Analytical proposal.

- Regarding the "Cognitive Dimension" (Figure 3) of the practice, the "Logic of Communication" stands out, gathering 51.5% of the cases (158 answers), followed by the "Logic of Responsibility," with 20.2% of the cases (62 answers), while the "Logic of Knowledge" and "Logic of Imitation" account for 13.4% (41 answers) and 8.8% (27 answers) of the cases.
- The "Affective Dimension" (Figure 4) shows that most of the responses concentrated on the sensations of "Knowledge/Awareness" (31.6%, 97 answers), "Trust" (20.2%, 62 answers), "Love/Friendship" (16%, 49 answers) and "Feel useful/Caring/Interest/Solidarity-hope" (12.4%, 38 answers). All these emotions grouped together concentrate then more than 80% of the answers. Finally, less frequently the respondents mention "Fear/Anxiety" (6.8%, 21 answers) and "Entertainment" (5.5%, 17 answers).

An interesting appreciation arises from the comparison of responses between those who re-send and those who do not. If we look at the cognitive content (Figure 5) of the practice associated with re-sending, we find that most of the responses are distributed uniformly across all categories, from which we could say that the "cognitive dimension" is not a significant factor in this action. This is not the case with what we call here the "Logic of Imitation," where we assume that a smaller set in the sample (13.4% of the total), which brings together motives linked to "keeping in touch," or deliberately seeking to "have some conversation" or "entertain/be entertained," predominantly brings into play this "cognitive dimension" of the action when re-sending messages.

Figure 4. Affective dimension.

If we pay attention to the affective content (Figure 6) of the practice, we find that the re-sending variable constitutes a factor that brings together two well-differentiated groups of "feeling practices": the action of re-sending is significantly associated with "Knowledge/Awareness," "Feel useful/Caring/Interest/Solidarity-hope," "Love/Friendship," and "Entertainment"; while "non-re-sending" seems to be associated with "Trust" and "Fear/Anxiety."

Figure 6. Re-sent/affective dimension.

It is important to emphasize at this point that the "affective dimension" seems to have a certain preeminence in explaining the action of forwarding/non-forwarding. If we observe the links between the cognitive and affective dimensions (Figure 7 and Figure 8) we can see some associations that qualify the alluded preeminence:

- The category that brings together a series of practices of feeling associated with fun and entertainment are linked, from the action of forwarding, with the "Logic of Imitation." That is to say, there is here a two-way connection between the cognitive and affective dimensions that is condensed in the action of re-sending. This speaks to us of the power, embodied in the expanded reproduction of audiences as the balance of the action, of the vertigo produced by the extortion of staying outside the digital-emotional world as a univocal feature of the politics of sensibilities.
- The practices of feeling linked to "awareness" and "love/friendship" seem to be the most frequent among those who forwarded messages as a way of intervening in the communicational process. On the other hand, feeling useful, supportive, hopeful, etc., explains a great part of the sensations of those who re-sent messages looking for some sense linked to the "common good." Both groups of sensations, as a whole, inform us about the horizon of the action embodied in the subjects, which is structured as the emotional basis of "the possible" in this digital world. In the face of the ominous nature of communicational processes, the need to become aware of and "care for" those close to us, to initiate solidarity actions, etc., emerges as sensations that paradoxically are articulated with the deliberate intention of intervening in communicational processes by amplifying them, or looking for the "common good"

by reproducing the practices of differential appropriation of information (not only as a common good but also as a strategic one).

- Finally, the feeling of trust (or lack of trust) describes the emotional state of those who decided not to forward messages, orienting the effects of their practices both in the communicational logic, and in the processes from which it approaches the "truth" ("Logic of Knowledge"). Fear and anxiety characterize the sentimental practices of those who did not send messages, looking to influence both the communicative process and participate in the construction of the "common good." In general, this group of sensations seems to structure two opposite poles (on the one hand confidence and on the other fear/anxiety) that give us insights about uncertainty as a central component of emotionality. This emotionality could be associated with "paralysis," "immobility" as a balance of personal experiences. Not to forward, "not to do" is not synonymous with destitution of the value chain of the audience as a commodity, in such a way that those who pretend "a certain quietness" as a way of "resistance to the "communicational logic," or those who due to fear or anxiety did not dare to forward the messages, are also a "transmission pulley" of the limited re-production of the audiences.

Gathering the tendencies that are described, we can advance in some statements of sense anticipation that allow us to understand how this particular association of cognitive and affective elements can be read as a particular configuration of the politics of sensibilities that underlies the digital practice. These policies constitute an interesting reading key regarding the predispositions with which subjects intervene in the interactions mediated by social networks.

Figure 8. Politics of sensibilities.

The first consideration arises from the question of what is the bodily disposition to participate in these kinds of digital interactions? How do these interactions occur? The data presented lead us to think that, beyond rational calculation, and framed in a series of specific cognitive logics, the digital practice in/by social networks involves a way of being for others. In other words, "being" in the expanding digital world increasingly implies "being" in social networks, and this presupposes, in addition to many other "skills," being able to "get emotional." Thus, a first point to note is that the affective dimension of the practice which refers to the interplay between the individual's sensations and social emotions seems to invade the cognitive contents with different senses, constituting a kind of "compass" that allows the individual to "navigate" the digital world.

Thus, the "logic of communication," as the predominant cognitive component (both in forwarding actions and in non-forwarding actions) appears to be traversed by various practices of feeling that underlie the communicational field. We can think in this respect that by sharing information an affective content is generated with multiple senses, all of which contribute to elaborate the "viral" dimension of the pandemic as an effect of "ideological violence" (Fuchs, 2014). That is to say, the pandemic constitutes (among other dimensions) first of all an "emotional product" that threatens and extorts those who cannot live it affectively in the networks. The irreversible balance of this practice is a world where the production, circulation and consumption of information-emotion turned into commodity is expanded and consecrated.

This refers directly to the notion of "audience commodification," but from the observation of a specific feature that emphasizes the place occupied by emotions: the data presented announce that the practices of feeling seem to organize the perceptions linked to the cognitive associated with them, constituting in themselves a condition and at the same time a specific content of the relationships in/by social networks. The substratum of value takes the form of the body's affective expression as a reservoir of motives for being in the network. Thus, the idea of production, circulation and "consumption" of information opens the way not only to the image of the "prosumer," but centrally to an "emotional prosumer." The notion of an "affective community" (Ahmed, 2019), as a concept that analyzes the function that emotions have in the construction of collective practices, leads us to think that digital affective exchanges build an "emotional platform" that works by organizing the metabolized energy flows in the processes of audience commodification.

The commoditization of emotions (as a process of delimitation and management of the practices of feeling) associated with the commoditization of audiences, provides the quality of "ambivalence" as a characteristic feature that ensures the effectiveness of these processes in digital contexts. As we observe, there is no difference in the cognitive logics that explain the passage from forwarding to not forwarding: however, the prevalence of certain sensations over the same logics builds a "plus" that allows agents to place themselves in the social world, and the process of audience commodification to expand with different values. Ahmed (2019) suggests that emotions are public, since they are constructed and signified through a collective imaginary. Based on this idea, she makes an analogy with Marx's vision of the movement of money and material goods, to develop the concept of "affective economies," which refers to the way emotions "circulate" and are distributed both in the psyche and in society. Re-appropriating this idea, and putting it in relation to what has been discussed about the commodification of audiences as well as the possibility of thinking from a sociology of

sensibilities, social emotions appear as that "plus" associated with sensations, which draw the conditions of operation of the "digital affective communities."

In this direction, the cognitive dimension of the practice informs us about a specific content of the regime of sensibilities as a condition of possibility of these "communities." A transversal look at the cognitive logics presented allows us to observe that what we here call "logic of communication," "of responsibility," and "of knowledge" are configured in the answers of the agents as a way of finding understanding about certainties, and the ways in which these are constructed and distributed. The fact that this cognitive framework is completed with the "logic of imitation" helps us to think that what is at stake is a profound process of reconfiguration of sociabilities, since this whole set of senses puts the "connection," already stripped of its technological garb, at the center of the scene as a condition of the collective body.

However, as we have been observing, if part of the expressed experiences refer us to a mutation of the sociabilities, another part of them refers us to the sensibilities as a central component for understanding this metamorphosis. In this direction, the preeminence of the affective dimension does not respond to an ontological consideration, but rather to an analytical one. It seems to be these explored sensations that orient the "connection" in a double sense: as a way of meaning for the cognitive dimension of the practice, as well as a "plus" that allows an interpretation of the content that constitutes the social emotions as a central component of the regime of sensitivities in course.

CONCLUSION

As an opening we would like to take up again the idea of "platform sensibilities" (Scribano and Lisdero, 2019) to refer to the cognitive-affective state linked - at least - to the following characteristics. In the first place, we should think of this particular state of the "politics of sensibilities" as processes extended in the "here and now" of labor times/spaces, but which operate in an expansive way from the mediations that enable relationships in/through the internet. Thus, as a regime, it stands out for the "intimacy" of the mechanisms that work as a necessary gear for the fluid deployment of the "digital production chain" ("audience commodification").

In this sense, sensibilities of platform imply a particular body policy, where sensitive terminals are processed by the phenomenal capacity of digital sensors to capture the creative forces of the bodies. This requires us to think beyond the processes of "consciousness" centered in the "brain," opening up questions about the complexity of the vital energies that are re-invented in a social body as a surface for the exploitation of digital processes. At the same time, these sensibilities also imply a "politics of emotions" that, as an accepted form of "feeling" oneself with respect to a range of expected practices, is related to a particular potential capacity to act on "others." These social emotions, connected to the sensations experienced by the agents (as we develop), constitute the conditions of digital labor. That is, they come as the mechanisms that occlude the corporal trace of digital energies from the affective tension that orient the perceptions in a "beyond" of the digital processes.

In this work, then, we have tried to move away from dichotomous models in the understanding of emotions, organizing the data from certain continuities of the process of

commodification, and following a certain analogy in the tensions between technology and the body. We resynchronize the notion of the body in the context of digital interactions from the basic certainty that if the "instruments" we use change, so do bodily sensations. The individual "supports" (in the Weberian sense) new forms of relationship, becoming the embodiment of digital technology. There are different ways of taking over the world, and technology is a new "logic of proximity." The body becomes an instrument, and in a way, it is a technology of communication with the other: the acts of bodily speech are modified according to the instruments, rewriting the body as the territory of life (and therefore of the productive processes in which it is inscribed). The problem of capitalism in societies 4.0 (Scribano and Lisdero, 2019) is the colonization of human and non-human nature, and "the digital" is no different from life. However, in the amplification of its re-productive processes, the logic of the commodity in-corporates the expressive forms of "being" in the digital world as a privileged component: being productive today is not only about "adapting" to the use of digital technologies, but above all about being willing to get emotional (not in any way).

Chapter 494

ECONOMIC, SOCIAL AND PSYCHOLOGICAL ISSUES OF SURVIVAL IN THE PANDEMIC: THE CASE OF RUSSIAN FEDERATION

Irina Burak* and Tatiana Razumova†

Lomonosov Moscow State University, Russian Federation

ABSTRACT

This chapter contains the broad economic and social review of the COVID-19 consequences which Russian Federation faces today. COVID-19 epidemic update had a great impact on all spheres, people's lives had changed dramatically: many people have contracted the illness, others lost their jobs and incomes, almost all were overcome with panic. So, the main objective of the Russian Government was to rapidly develop a program of urgent response in the sphere of healthcare as well as in preventing deep negative consequences in decrease of peoples' incomes and welfare. The special measures of economic and social support were undertaken by the government towards SMEs and people under great risks of poverty. Volunteers' activities aimed at care of elderly people under the isolation restrictions became widely developed. To prevent the risk of contamination lots of people in different spheres were urged to work distantly, this process was supported by wide access to informational technologies and equipment and well-developed skills of specialists. Still, for many companies it was a severe challenge which required training of personnel and new management tools. During the isolation period distant professional learning was of great importance and popularity: it helped to prepare people to overcome the crisis with marketable knowledge and skills.

INTRODUCTION

The Russian Federation, together with other countries, faces serious challenges due to the pandemic. From February 2020 till April 2020 there were slowly increasing rates of infection in Russia, but then the situation became worse, so the Russian government enforced quarantine from the 30th of March. Since March 30th, restrictions were imposed on movement across the Russian border. They concerned automobile, railway, pedestrian, and river traffic, and mixed checkpoints at the border, as well as the land section of the Russian-Belarusian state border. Moreover, there were serious restrictions inside the country: on transitions between Russian regions and even between districts in big cities. A lot of attention has been paid to maintaining immediate medical services for everybody who needed them. All these efforts were implemented efficiently and successfully, and rates of contamination began to fall. But when the restrictions were lifted and people began to live their usual lives, we all faced the second wave of the Coronavirus pandemic. As of the 25th November, there are 2,162,503 Coronavirus cases in Russia, among them 1,660,419 recovery cases and 37,538 fatal outcomes. Of course, Moscow, Saint Petersburg and other big cities are the most affected (Russian Government, 2020). In such a difficult, worsening epidemiological situation, the government needs to respond quickly to new challenges and take the most effective measures to mitigate the situation and its consequences; organizations need to ensure the safest working conditions for their employees with the maximum preservation of productivity, and it is very important for citizens not to give in to panic and to observe the prescribed precautions as much as possible. That's the background we're seeing today.

SOCIO-ECONOMIC ISSUES

The first wave of the Coronavirus pandemic lasted from the second half of March 2020 till August 2020. The second wave of the pandemic, started approximately at the beginning of September 2020, slowing down the recovery of the labor market in Russia, but the number of vacancies did not decrease, as Head Hunter's research showed. According to that data, the level of competition for jobs in mid-autumn dropped slightly compared to the "before pandemic" period. On average there are six active resumes per vacancy against seven in February-March. In the second half of October the labor market experienced the second wave of the epidemic, the number of vacancies in the labor market did not fall, but the recovery trend observed since June slowed down. Thus, in October the number of vacancies published at hh.ru exceeded the figure for September by only 1%, while the annual growth is more tangible - 18%. In early November in most regions, there was a slight decrease in demand. The number of active vacancies increased only in the North-Caucasian Federal District. In early November the demand for specialists in consulting, transport and logistics, as well as in civil service, increased. The maximum decrease of demand is observed in-home staff, in tourism and hotel and restaurant businesses, as well as in the sports and beauty industries (Business Journal, 2020).

The economic situation of the Russian population during the period of self-isolation has deteriorated. According to the United Credit Bureau, in the second quarter of 2020 (April-June), working Russians lost 841 billion rubles of income. This is the equivalent of 16 million

average wages. The main reason for the losses is part-time work or a reduced working week. Such measures were used by businesses to optimize costs. During the pandemic, the government financially supported certain groups, such as families with children, and subsidized entrepreneurs who did not fire employees because of the crisis. Therefore, large-scale cuts were avoided. However, after self-isolation, the number of announcements about the sale of businesses in cities with a population of millions increased by 28% - this is indirect evidence that entrepreneurs were on the verge of bankruptcy. It can be supposed that as soon as the pandemic goes down and the government stops subsidizing businesses, small companies will start closing down and unemployment will increase (Brusentseva, Vtoraja volna koronavirusa i obshhie sny: dajdzhest trendov obshhestva № 20, 2020).

During the Coronavirus lockdown in Russia, unemployment rose by 30% on average in the regions. Many companies reduced their employees during quarantine or ceased to exist at all. Moscow, St. Petersburg and the Moscow region were the most affected by layoffs, while 3.5 million employees have been laid off since the beginning of the pandemic. According to the Russian Federal State Statistics Service (Rosstat), the total number of unemployed in the country exceeded 4.5 million in May 2020, and the unemployment rate reached a record 6.1%. In July, registered unemployment growth slowed by a third, and the market began to slowly recover after restrictive measures were lifted (Sycheva, 2020).

The social network "Odnoklassniki" and the research center "ResearchMe" conducted an online survey on women's income during the Coronavirus pandemic. The study involved 1,603 women over the age of 18. One in five women claimed they had lost their jobs during the pandemic. Most affected were the respondents between 18 and 24 years of age (30%). Among those who lost their jobs during the pandemic, about 36% have not yet found new employment. Women aged 25-34 noted that employment was hindered by the presence of a child (22%), while in the group of respondents over 45 years old the cause of difficulties in employment most mentioned was that of age (49%). According to the survey results, 61% of female respondents who worked during the pandemic experienced a decrease in their monthly income (Telegraph Agency of the Soviet Union (TASS), 2020).

The pandemic and general quarantine have confused all previous plans of employers. Some companies have started to send employees on vacation for an indefinite period and reduce their salaries, and most employers are waiting for the situation to develop and have suspended recruitment, while some continue to hire staff. According to the recruitment company Antal Russia, 12% of employers stopped recruiting employees in February and 40% in March. The share of those who planned to fill vacancies decreased from 47% to 21% during the month. 75% of companies have already reduced their staff costs due to coronavirus. 54% cancelled team retreats and teambuilding, 47% saved on travel expenses (business trips were cancelled), and 43% reduced the cost of education and training. Furthermore, 26% of respondents said they are looking for ways to avoid salary cuts and the cancellation of bonuses (Podtserob, 2020).

According to the KPMG survey "HR Actions in the Situation of the Pandemic," 49% of respondents - large companies - have already translated face-to-face interviews fully online, and 22% - partially. In the next year, 59% of companies will optimize personnel costs, 44% will switch to a new management model (flexible schedule, remote work, online recruitment), and 41% will automate personnel management processes. The study also says that after the end of the crisis, regular management practices will include the tools that had to be switched to during the epidemic: remote work (36% of respondents), online recruitment (46%) and

online training (41%) (Podtserob, 2020). In this respect, Coronavirus has given a powerful impetus to cloud technologies. In the first half of the year alone the demand for them grew by 30%. Thanks to the migration to the cloud, companies working mainly in the delivery of food, FMCG goods and electronics, managed to survive organizational “overloads” associated with the transition to the “remote.” While the sites of those companies, which in the old days relied on their own data centers, regularly lost profits. Quarantine and fear of infection led to strong growth in e-commerce and e-retail. Thus, according to the research center “NAFI,” 67% of Russians during self-isolation ordered food and non-food products in online stores. The share of online purchases in the FMCG market almost doubled compared to 2019: from 1.9% in 2019 to 3.2% in March 2020. It is expected to grow to 4% by the end of 2020. Moreover, isolation has led to accelerated modernization of remote communication technologies in several areas at once. On the one hand, many companies have started to establish new technology solutions, which were previously considered “non-priority” to ensure synchronization of all processes outside the office, as well as to integrate chat bots and applications for the analysis of big data (Sysoev, 2020).

On the other hand, for the first time, telemedicine became a truly global trend. For example, in the first half of 2020, remote medical consultations through mobile applications and online services increased by 177% compared to the corresponding period in 2019. In response, both the development of algorithms for medical artificial intelligence (AI) and the development of AI services for the decoding of medical images have intensified (Sysoev, 2020).

The market situation has formed a “window of opportunity” for all digital segments of the economy. E-commerce, companies offering digitization business services, online video, online games and many other digital services are now growing. The field of online education is one of them. Schools, universities and kindergartens forced to switch to remote operation in an accelerated mode were generally not ready for this “new normality.” Not all teachers have been able to quickly restructure the learning process “from a distance,” arrange lessons and lectures in such a way as to retain students’ attention and move to an individual, more flexible teaching process. Besides, not all teachers have been able to quickly adapt to new learning technologies on online platforms. Parents were also not ready for a remote format, mainly for combining work and supervising their child’s learning (Sysoev, 2020). The Russian school education system was not ready for online education. The technical equipment of schools, teachers and pupils still leaves much to be desired. At the moment of urgent changes teachers did not know how to teach effectively online and could not get fast methodological and administrative support from above. It was a systemic failure which, although not officially recognized, was understood by all participants. At the same time, the Ministry of Education tried to face the truth and take quick steps to correct various processes, including involving commercial companies and platforms (Mjagkov, 2020).

Recently, together with the research group EdMarket and TalentTech, one of the largest EdTech companies in Russia “Netology-groups” has conducted a study of the online education market: in 2019 its volume amounted to 38.5 billion rubles. With “pre-quarantine” growth rates by 2023, this figure would reach 60 billion rubles. It’s worth noting that Edtech grew significantly before Coronavirus and the pandemic has only sped it up. For example, in “Foxford” - a project focused on schoolchildren - more than a million new users registered during the first week of quarantine (Spiridonov, 2020).

The free access to courses opened by many online platforms is an opportunity for mass users to at least try distance learning in its various forms. But it may take time for everyone to get used to the online format and start learning fully. The trend for digitalization of business, which has been going on for several years, but during the pandemic is more relevant than ever, affects business education as well. On the one hand, it may seem that the crisis is hitting hard on the sector of business education, making it less popular due to the worsening economic situation. But this is not true; traditionally all segments of business education, including MBA programs, are in great demand during the crisis in the market. Managers and top managers today are most eager to learn how to run a digital business: business strategy development, teamwork, management and administration, sales and marketing with a focus on digitalization. And the interest is observed in representatives of companies from all market segments, even such conservative ones as medicine and construction. And business education is ready to take into account the needs of the business, to adapt to them and offer relevant and current knowledge. Changes in the employer's requirements for employees are based on changes in the set of competencies for certain positions. For example, to perform the functions of the head of the planning and financial department, a leading economist does not need to obtain a second higher education; in addition to the available knowledge in the field of economics and finance, it is enough for him or her to master managerial competencies. Through further professional education, the employee can fill in gaps in the required skills in a short period. In times of economic instability, employees may face the challenge of retaining them in the workplace, which is also possible through further professional education programs that will strengthen the employee's competitive position in the labor market (Razumova & Burak, 2019).

The initial increase in productivity shown by workers transferred from home to work was quickly replaced by an increase in fatigue. There were several contributing factors at once: lack of workspace, specific 'home factors' such as children, relatives or neighbors that constantly distract attention, lack of communication in the team, and excessive or minimal control by the employer. All this has become an obstacle to normal work, which for many has resulted in a loss of motivation to work. The uncertainty factor associated with the unstable economic situation and layoffs, which affected many industries, was also imposed on this. So, the spring prophecies about the "convenience" and "efficiency" of remote work were false for many people. On the contrary, we can say that today a new privilege has been formed - to work in an office at least for a few days a week. In fact, as JLL's global research shows, post-pandemic demand for office space may not be so different from recent trends. Instead, the way space is used will change. Lower occupancy levels will be compensated for by allocating more space to each workplace. Employers will pay more attention to supporting direct communications, learning and development, creativity and collaboration - the real reasons why people want to work together (Sysoev, 2020).

Sharing services are gaining popularity on the labor market, and at all levels - from simple tasks to expensive consultations. For many of those who have lost their job, but have the right skills, it becomes a way to stay afloat, and for companies a means to save money. Uberisation is not just a cab service: business in Russia uses sharing to get the expertise of highly competent specialists. Another common type of request on the sharing platform is an independent opinion. Companies focused on rapid growth are not always ready to spend time on long study and long decision-making when the issue can be resolved with independent analysis from an external expert within an hour (Bindjuk, 2020).

Because of the Coronavirus pandemic, it became more difficult for a migrant worker to come to Russia to work. According to the Ministry of Internal Affairs, in August 2020, 33.9 thousand people received work permits; a year earlier there were 82.4 thousand. According to a study by the Center for Strategic Research (CSR), 40% of companies are now experiencing labor shortages. The deficit of couriers and cab drivers is especially acute. The business is again moving employees to remote locations and the number of orders in online stores is growing. However, due to the outflow of migrants, there is no one to deliver additional orders. Many residents of the regions, who lost their jobs in the capital during the pandemic, have returned home (Brusentseva, 2020). For regional companies, who have vacancies, this is a chance to hire good specialists and implement new projects.

PSYCHOLOGICAL ISSUES

Sudden changes have now occurred in everyone's lives. They happened faster than the human mind can adapt. The overall level of fear and anxiety, which has increased significantly due to the pandemic and the global economic crisis, may lead to unwanted long-term psychological consequences, experts believe. On the one hand, the fear of a future filled with uncertainty may not only increase the already high level of anxiety but also lead to a deep depression, especially among the poor. On the other hand - for people with a genetic predisposition to some forms of obsessive-compulsive disorder (OCD) - i.e. various obsessions leading to compulsive actions - COVID-19 stress can only exacerbate OCD.

Compared to other generations, during the period of self-isolation, "zoomers" (youth aged about 11-25 years) felt the worst. Mainly, they complained about a feeling of boredom (51%), less physical activity (47%) and an increased sense of loneliness (41%). They also expressed concern about the negative impact on health due to increased screen time: 31% vs. 25% of millennials and 14% of Gen X. The younger generation was also more likely to experience increased anxiety and stress compared to the older generation: for example, almost half of the "zoomers" said they were worried about COVID-19 (Sysoev, 2020).

Brand Analytics decided to analyze how the COVID was discussed during the year in Russia, Ukraine, Kazakhstan, Belarus, Armenia and Moldova. Where the COVID-anxiety was higher, what are the dynamics and platforms for discussion, and whether there is a correlation between the dynamics of references and the dynamics of morbidity. To understand how much the topic of Coronavirus excited people in different countries from the full flow of messages in the social media of each country, publications with mentions of COVID-19 was highlighted. Taking into account the population size, the index of "COVID-anxiety" equal to the number of mentions of the virus subject for a day for every 10 thousand of the country's population was calculated. The peak of anxiety everywhere occurred at the end of March. The greatest degree of anxiety was demonstrated by Russians and Moldovans. Inhabitants of Ukraine and Belorussia were less worried; the latter joined the discussion of COVID later than others. In Kazakhstan and Armenia, users were less actively discussing coronavirus publicly. In the central regions of Russia, residents met the second wave more calmly. The anxiety increases with the distance from the center (Cherniy, 2020).

The top 5 the most "alarming" regions look like this:

1. Magadan Region - 132 (COVID-anxiety index)
2. Chukotka Autonomous Okrug - 127
3. Republic of Crimea - 123
4. Kurgan region - 107
5. Jewish Autonomous Region - 97

The top 5 “quietest” regions were:

1. Chuvash Republic - 35
2. Kabardino-Balkarian Republic - 35
3. Pskov region - 35
4. Sakhalin Oblast – 35
5. Republic of Dagestan – 34 (Cherniy, 2020).

According to the All-Russian Public Opinion Research Center (VTsIOM) survey, 15% of Russians believed that Russia was going through the worst period of the pandemic in September 2020. Another 16% answered that all difficulties are over. But the majority (60%) is sure that hard times await them in the future. In particular, the difficulties will be related to the economic crisis. But this is not the only concern of Russians (VTsIOM, 2020).

The Public Relations Development Company (PRDC) has published a new “National Index of Concerns,” a survey that shows what fears are prevalent in society. PRDC experts assess phobias by analyzing media materials and discussions on social networks. To make the rating, they use the media young index (MJng). It is calculated as a ratio of three variables: the frequency of appearance of a worrying topic in the media, its popularity in social networks and the duration of discussion of the topic. In the course of the study, PRDC analyzed 130,000 media publications and 1 million posts in social networks from June to the end of September 2020 (Brusentseva, 2020).

These are the four reasons why Russians are most worried:

- The second wave of Coronavirus (total index 353.27);
- Russia’s participation in the political crisis in Belorussia (129.99);
- Dismissals and unemployment (122.06);
- Environmental pollution (63.06).

Interestingly, the first three problems are most frequently mentioned in media reports, while the climate agenda is discussed in social networks and media with equal frequency (ratio 1.09). This indicates the relevance of the topic for society and the involvement of Russians in the discussion (Brusentseva, 2020).

Due to social isolation, time spent with the family has naturally increased, and this can play an important role in the next generation of children. The fact that parents accustomed to business trips and office work have settled at home and become more flexible in structuring time can lead to a change in priorities within the family through a more balanced distribution of work and personal time. A truly comfortable family environment will result in parents being able to work more efficiently. By the way, transformations can also happen to children: although COVID-19 has further strengthened the role of technology in the life of the “Alpha

generation,” the virus has emphasized the value of personal communication for them (Sysoev, 2020).

According to a survey of the research company Ipsos, after the abolition of self-isolation, the level of happiness in Russia increased by 11%. This is a record figure among 27 countries in which the study was conducted. The same high value was recorded in China. Despite the sharp increase, Russia took only 18th place in the ranking of countries in terms of happiness. In first place was China, as 94% of the Chinese consider themselves happy (Ipsos, 2020).

Table 1. Level of happiness

	Dec-11	May-13	Mar-17	Feb-18	Jun-19	Aug-20	Change since December 2011	Change since June 2019
Global Average	77%	77%	61%	70%	64%	63%	-14%	-1%
China	78%	79%	84%	85%	82%	93%	15%	11%
Netherlands						87%		
Saudi Arabia	83%	74%	75%	76%	78%	80%	-3%	2%
Canada	85%	83%	81%	81%	86%	78%	-7%	-8%
France	84%	81%	68%	77%	80%	78%	-6%	-2%
Australia	86%	84%	72%	82%	86%	77%	-9%	-9%
Great Britain	79%	81%	71%	78%	82%	76%	-3%	-6%

The increase in the level of happiness in Russia in the short term after the period of self-isolation can be explained by the removal of restrictions on such important universal things as meetings, personal communication, and free movement. During the period of self-isolation people have never felt their importance and value, and after the removal of restrictions a return of the lost and the feeling that the pandemic has retreated, allowed many to feel the tide of happiness in life (Ipsos, 2020).

The things that bring Russians happiness are children (59%) and relationships with a partner (56%). The feeling that their life is full of meaning was mentioned by 49% of respondents, another 45% of respondents chose good living conditions and financial well-being, and a little less - 44% - health (Ipsos, 2020).

Compared to 2019, the prevalence of happiness globally has remained nearly unchanged. It has increased by at least 5 points or more in six countries, most of all China, Russia, Malaysia, and Argentina. It has decreased by 5 points or more in 12 countries, most of all Peru, Chile, Mexico, and India (Ipsos, 2020).

POLICY ISSUES

Measures to support the economy and population have been taken in different countries of the world. The introduction of quarantine measures has a serious impact on the economies of all countries. Many kinds of activities stop at once. The production scale of many enterprises is limited. That is why the support measures are very important. Several support packages have also been approved in Russia: these are point measures to support the population and several business sectors, which we will consider in detail below.

The Government of the Russian Federation is constantly developing and taking new measures to counter the spread of new Coronavirus infection. They can be divided into two groups: social and business support measures. The first group includes:

1. Benefits for families with children. All families with children under the age of 16 received financial support, and families whose average per capita income does not exceed the minimum per capita subsistence level established in the constituent entity of the Russian Federation are entitled to monthly payments.
2. Sick leave for workers over 65 years of age. Working citizens of 65 years of age or older, observing the regime of self-isolation due to Coronavirus, who have not switched to remote work and are not on vacation, can remotely issue an electronic sick leave.
3. Support for the unemployed. Citizens who have lost their jobs will be able to apply through the portal "Work in Russia" for help in finding a job, as well as to apply for registration as unemployed and apply for unemployment benefits online. Additional payments are also granted to citizens who are dismissed and recognized as unemployed and have children.
4. Helping people with disabilities. Almost all interactions to formalize a disability and receive the corresponding allowance have been transferred online. Individual rehabilitation programs are automatically implemented without additional applications.
5. Support for employees of social institutions. Additional payments apply to those institutions that have entered quarantine - that is, where employees worked for at least 14 days inside the institution to minimize the risk of infection of citizens living there.
6. Support of employees and volunteers. Special payments are made to employees of state and non-state organizations and volunteers who have accepted accompanying and temporary accommodation, including temporary care, disabled persons, older citizens, orphans and children without parental care, social service organizations and orphanages.
7. Assistance to tourists. Citizens who have planned a trip from the beginning of the restrictive measures until June 1, 2020 will be able to receive a refund for a disrupted trip. In case of cancellation of a flight abroad, which should take place during the period of prohibition of international air travel, the passenger will be refunded the full amount for the ticket. Besides, there is an organized return of Russian citizens from abroad. For all who find themselves abroad and are unable to return to Russia

due to the spread of new Coronavirus infection, the necessary social support is provided.

8. Extension of documents. Passports and driver's licenses that have expired or expire between February 1 and July 15, 2020, inclusive, are considered valid.
9. Credit vacation. This is a grace period for possible reduction or suspension of regular payments on the loan for up to 6 months. They are granted to citizens who have difficulties with payments on loans or credits, if their income for the month preceding the date of application, decreased by at least 30% compared with the average monthly income in 2019.
10. Moratorium on payment of penalties for housing and communal services. It is forbidden to levy penalties for late or incomplete payment for housing, utilities and repairs. It is also prohibited to limit the provision of utilities in case of their late payment by citizens.
11. Monitoring of essential goods. In order to prevent the spread of new coronavirus infection in Russia, a list of non-food items of prime necessity and rapid monitoring of their availability in trade organizations was compiled so that there would not be a shortage of these items. The list of essential goods includes disinfectants and personal protective equipment, hygiene supplies and detergents, baby products, pet food, various fuels, candles, and matches. State authorities of the subjects of the Russian Federation have the right to make changes in the list of non-food items of prime necessity at the regional level based on the sanitary and epidemiological situation in the region.
12. Sale of medicines online. Medicines released without prescription can be purchased through the Internet with home delivery. It is not possible to buy prescription drugs, as well as over-the-counter drugs, narcotic and psychotropic drugs, alcohol-containing drugs with a volume fraction of ethyl alcohol exceeding 25% via the Internet (Russian Government, 2020).

The second group contains:

1. Bankruptcy moratorium. Acceptance of creditor bankruptcy applications from creditors is suspended. The courts also suspend proceedings in accepted cases where bankruptcy proceedings have not yet commenced. The debtor is relieved of the obligation to go to court if there are signs of bankruptcy, but the right to do so remains.
2. A moratorium on business audits. Suspends field audits of small and medium-sized businesses. All licenses and permits are automatically renewed for six months. Only unscheduled inspections are preserved, the basis for which is harm to life and health of citizens, the emergence of emergencies of a natural and man-made character.
3. Credit vacation for business. Entrepreneurs can get a grace period on the loan for 6 months, as well as count on reducing the amount of deferred debt due to federal subsidies for banks, if the credit organization participates in the program of the Ministry of Economic Development. This measure applies to SMEs working in the most affected areas: air and road transport, tourism, the hotel business, catering, culture, entertainment and leisure (including cinemas, museums and zoos), physical

education and sports, conferences and exhibitions, consumer services to the public, dental practice, additional education, and retail trade in non-food products.

4. Interest-free loans for salaries. Large, medium and small businesses, as well as individual entrepreneurs from the most affected industries, can take an interest-free loan from the bank for six months to pay salaries to employees. Credits for small and micro businesses will be provided by the bank, taking into account the main and additional OKVED. For large and medium-sized companies - only the main.
5. Decrease in insurance premiums. For organizations and private entrepreneurs included in the Single Register of SMEs, the total amount of insurance premiums is reduced from 30% to 15%. The rate of contributions to the Pension Fund of Russia will be 10%, to the Federal Compulsory Medical Insurance Fund - 5%. Contributions to the Social Insurance Fund (for disability and maternity) are not paid.
6. Tax vacations. This means that almost all taxes are deferred for companies in the ten industries most affected by the epidemic and part of the taxes for all other entrepreneurs.
7. Postponement of rent payments. Delayed payment of rents applies to state, municipal and private property.
8. Assistance to exporters. The Russian Export Center provides businesspeople with targeted consultations taking into account the situation in the industry and the specifics of the enterprise. The operational headquarters of the Russian Export Center helps solve logistics problems and obtain financial support in connection with emerging cash gaps, assists in concluding new export deals and advises on a wide range of issues in the sphere of certification, subsidies, cooperation with customs authorities, etc.
9. Non-refundable subsidies. Small and medium enterprises from 11 affected industries can benefit from direct financial support from the state. Entrepreneurs can receive an amount equal to the established minimum wage per employee.
10. Extension of licenses. If a company is engaged in licensed activities, there is no need to renew licenses in 2020 - many licenses are automatically renewed for one year.
11. Support for systemically important enterprises. System forming enterprises are companies that have a significant impact on the development of the country's economy, provide the greatest employment in their industries and are the largest taxpayers. The government has developed several special measures for system-forming enterprises: preferential credits for replenishment of working capital and maintenance of employment, special conditions for obtaining deferral or installment payments for some tax payments with payment deadlines in 2020, credits at a preferential rate can be obtained by subsidiaries of system-forming enterprises, as well as their parent companies. Besides, systemically important companies that are at special risk can also apply for subsidies to reimburse production, work and service costs and government guarantees necessary to restructure existing loans or issue new loans and bond issues.
12. Non-performing loans. Such loans may be claimed by enterprises from affected industries, as well as socially oriented non-profit organizations. For enterprises that retain at least 90% of their employees, the loan will be written off along with interest - the state will pay the entire amount. If at least 80% of employees remain on the

staff, the entrepreneur will have to repay only half of the loan and the interest on it (Russian Government, 2020).

Thus, we see that we are talking about supporting the population and business through a softer monetary policy, accompanied by extensive budget guarantees, which reduce the risks of bank lending. It should be noted that the measures taken by the Russian government have helped the population and business to survive difficult times, as well as kept the country's economy from collapse, preventing a sharp downturn.

VOLUNTEER ISSUES

Within the framework of the All-Russian action of mutual assistance during the Coronavirus Pandemic "My Vmeste," volunteers help elderly people in the delivery of products, medicines and necessities, they also perform such functions as psychological and legal advice, online assistance, and volunteers with specialized education help in medical organizations. The target audience for assistance comprises elderly people and citizens with low mobility (My Vmeste, 2020). Appeals are accepted twenty-four hours a day on a "hot line." There are four main volunteer focus areas:

1. Buying and delivering products, medicines and essential commodities. People who are now at home in self-isolation due to Coronavirus need assistance in buying and delivering products, medicines and household goods. Volunteers purchase everything they need and bring it to beneficiaries observing all safety precautions.
2. Assistance with medical organizations. Due to the high load on medical staff, assistance in patient care, manipulation, document management and patient routing is required. Volunteers are distributed according to their specialization. Non-medical assistance in this area can also be joined by those who do not have a medical education.
3. Providing psychological assistance. Due to the wide spread of various information about Coronavirus infection, people are not always able to perceive it adequately, and there are stressful reactions. Volunteers with appropriate training provide psychological support to people by telephone and text consultation. To become a volunteer in this area, individuals need an education in psychology.
4. Help in call centers. Patients with a mild course of the new coronavirus infection are given outpatient treatment. Volunteers make calls to these patients using prepared scripts to monitor the dynamics of their condition and refer them to the doctor's surgery if necessary. Volunteers also respond to citizens' questions about the coronavirus, talk about its prevention and diagnosis, report the results of tests, and pass on necessary information. General volunteers and volunteers with medical education can work in this area (My Vmeste, 2020).

Each volunteer must take a distance learning course on the following topics:

- Hygienic norms for volunteers;
- Mechanism of providing volunteer assistance to elderly people;
- The specifics of interaction with elderly people;
- The actions of volunteers in emergency and non-standard situations (My Vmeste, 2020).

After that, they will receive a face-to-face briefing on safety at the headquarters in groups (up to 20 people) or individually. Then they receive an accreditation badge and admission to work, after which they undergo a check-in procedure before starting work: temperature measurement, safety briefing and receiving individual safety kits (My Vmeste, 2020).

To avoid cases of fraud, applicants are informed about the identity of the real volunteers:

- Volunteers wear a special badge and a passport.
- Volunteers are provided with personal protective equipment: a disposable medical mask, gloves and antiseptics.
- Volunteers do not enter the apartment/house.
- The volunteer knows the beneficiary's application number and must inform him/her at the beginning of communication.
- You can check the identity of each volunteer by contacting the regional volunteer organization (My Vmeste, 2020).

This is the largest, but not the only, action of mutual aid in Russia that appeared during the epidemic. Obviously, in such a difficult period, the main pressure falls on medical personnel, who also need support, including of a moral kind. For example, in Blagoveshchensk there is an action "Doctors are our heroes," where the city entrepreneurs collect gifts for medical workers to support them during the pandemic. They buy medical hand creams, moisturizing facial masks, honey and other sweets, which they put into gift sets and give to doctors who work with patients with COVID-19. Gifts are bought at the expense of entrepreneurs and citizens who care about them. Businesspeople also donated fruit and fresh baked goods to the staff of the emergency station and Blagoveshchensk city hospital. The initiative group plans to form gifts for medical workers from hospitals in the region. The coaches and sportsmen of "Mashina" club in Blagoveshchensk help doctors unload medicines and furniture, which were transported from one medical institution to another to equip infectious diseases hospitals (My Vmeste, 2020).

CONCLUSION

Nowadays it is obvious that such a great pandemic will have a long-lasting and even controversial effect on all spheres of people's lives. And its consequences are highly dependent on the expediency and efficiency of specific measures undertaken by the government and peoples' economic and social behavior. Of course, the Coronavirus pandemic has such a huge scale that preventing and defeating it cannot be an objective of each country in particular. There must be a strong collaboration between countries, at least between those who have common frontiers.

Chapter 495

LONG LIVE TO THE URBAN FLESH

Fabio La Rocca*

LEIRIS (Researcher center of social imaginary),
University Paul-Valéry Montpellier 3, France

Panic on the streets of London
Panic on the streets of Birmingham
I wonder to myself
Could life ever be sane again?
The leeds side-streets that you slip down
I wonder to myself
Hopes may rise on the Grasmere
But honey pie, you're not safe here
So you run down
To the safety of the town
The Smiths – Panic (1987).

ABSTRACT

In the present chapter we bring some reflection about changes of the current reconfigured urban space and the orientation of a revaluated vision of ecosophy with some specific elements of the ambiance that we can observe in the daily experience. With this structure, we build in our way a kind of sensible thought to elucidate a vision of some forms of urban social dimension. Our intention in this hot-debate aims to show some fragments constructing a particular vision of the spirit of the time in order to analyze the actual socio-urban dimension. In this perspective, will bring together some goals as the illustration of the actual city, the experience in the post COVID19 situation, the idea of proximity, the new vision of ecological sensibility, where each of them encloses other peculiars aspects of our experience of the social urban world.

Keywords: urbanity, emotions, pandemic, COVID19, ecosophy

INTRODUCTION

How to think the city and its spaces in the actual social situation? We assist in a renewal of the approach of the way to live in urban space and the changes in the lifestyle. Is the city in crisis? It is dead? What is its future?

The explosion of the epidemic situation has generated a particular condition in the whole world where the imposition of ‘social distancing’ and the political interventions about the virus Covid 19 have transformed the face of the city. One of the first impressions is that we witness a materialisation of post-apocalyptic imaginary, the catastrophic dimension of urban space where the persons disappear and the city becomes empty of social life. This is a sort of imaginary to live on new ruins of an actual social world where all the images that circulate on social media, on tv, web or journals, exhibit the empty cities as we lived in a kind of science-fiction dimension: Into the void.

Despite all, the first global lockdown shows us a ‘particular beauty’ of the cities: it’s a paradox maybe, but strangely all the images that we have consumed can be considered as ‘the unsettling beauty’ or a ‘sadness beauty’ of global cities. The images of empty cities that we observed, like Time Square in New York that is usually a pulsing heart, or California Street in San Francisco without the full dimension of tram and cars, the alleys of Venice, Plaza Mayor in Madrid, Ponte Vecchio in Florence, Champs Élysées in Paris, habitually places of the crowd and animated temporalities like many other examples. This gives us the feeling that the city without the human is more romantic, attractive, scenic! Everyone in front of these images can have the impression of this ‘strange beauty.’

Our intention in this reflection, is to show some aspects or better some fragments constructing a particular vision of the spirit of the time in order to analyze the actual socio-urban dimension. The fragments are like images of thinking, as the work of Walter Benjamin teaches us, to illustrate the signs of our present and re-think our time. In this perspective, will bring together some goals as the illustration of the actual city, the experience in the Covid situation, the idea of proximity, the new vision of ecological sensibility, where each of them encloses other peculiar aspects of our experience of the social urban world. In the first step, we clarify the image of the city through the effect of the pandemic situation and after concentrate the reflection about how the Covid affects our life in the urban and the interior dimension with the particular effect of digital experience. After that, the discussion will be oriented towards the notion of proximity and the semiotic changes of the current reconfigured urban space and the orientation of a revaluated vision of ecosophy with some specific elements of the ambiance that we can observe in the daily experience. With this structure, we build in our way a kind of sensible thought to elucidate a vision of some forms of urban social dimension.

SHORT DEBATE: THE CITY

The desert city, the phantom city, or the silent city where one can just listen to the sound of nature. These are the impressions of a fascinating atmosphere where the calm dominates transforming the city into a unique historical moment. We can witness this show during a digital promenade on Instagram where is possible to rediscover the splendor of the city. This

illustrates a kind of impossible dream of seeing the beauty of the landscape without traffic, pollution, noises... The pandemic is affecting the emotional aspect of the images that circulate as conversational moments of daily life shared by the internauts (or netizen). They create a mosaic of this kind of landmark proving the world as a post-apocalyptic appearance. During this period, we have been spectators of external life from the interior. Our windows represent a porosity instrument, a medium to look at this spectacular desert. At the same time all the web's windows permitting us to circumnavigate all over the city of the globe to assist at this world in ruins. In this perspective, we can think, in reference to the theory of Walter Benjamin, at a compenetrating of spaces. That would be a duality where the urban space has a texture of an image like a new kind of phantasmagoria. It would allow us to dream, from the windows, the external urban life. This particular porosity represents an allegoric form of presence with an emphasis on emotions and feelings. Emotions must be understood as a social language, a collective expression, in the perspective of Marcel Mauss (1921). In our reflection, we can see how the extension of the interior of our apartments during the lockdown was exteriorized from the window to create a social manifestation of an emotional tribality (Maffesoli, 1988). It's an emotional resonance that the people create with this kind of 'sociology of balconies.' It became an expression to this extension from inside to outside, the intimacy became extremity (*extimité*) according to the analysis of the French psychiatrist Serge Tisseron. Our balconies and windows, from Paris to Naples, from New York to Barcelona, etc., testified this desire to make visible the aspects of our social existence without the possibility to be on the street. It gave the possibility to live the street through the lockdown. We can conceive them as an 'opening on the world' (Teyssot, 2009) or also as an instrument of political act. Show drawing of children, clapping, sing together as a kind of flash mob, the music on high volume are some actions that people organize from this particular space, the balcony, became for a special period the 'new street.'

This special emotional moment describes an imaginary of 'cultural apocalypse,' using here a terminology of the Italian anthropologist Ernesto Di Martino (1977), that indicates a relevant change transforming the entire community of people. The apocalypse means the end of a paradigm and its cultural organization that generate the production of a new kind of behavior, thought and interests. Each epoch can have its 'end of a world' that signifies a deeper social change and, in our reflection, an actual reconfiguration of urban life. The question, following Di Martino, is about the 'how.' In our consideration how is or must be the human in the city and this 'how' represents an ontological question of the presence and the way to be in the world and renovate it through different forms. How is the way to be in the social world and in the urban dimension in this particular *zeitgeist*? The approach of Georg Simmel concerning the idea of sociology as *nova scienza* (a notion used by Gianbattista Vico) is relevant in this consideration. Reality isn't static but always in movement and the same goes for the city and its urban atmospheres. So, we must observe this reality in movement and try to put in evidence some forms, some essential characters. In this direction the modalities we inhabit the world are in relation to the urban sphere. In this case, the balcony assumes a significant dimension of social interrelation fusing with the digital space to create a fortification of the social connection.

THE COVID19 AND THE EXPERIENCE

COVID19 instils emotional affectivity of the human action also developed via the web life's experience creating. Therefore, it becomes an expressive space, or a 'grammar of experience' (Goffman, 1991) made possible through the urban photos shared by the citizens to show the reality of the present city. It shows a city of ghosts lived by images that remind us of an imaginary post-apocalyptic. This is carried by science fiction or from the narration by tv-series and cinema that absorb reality in a kind of melancholic feeling. This can be the logic that constructs a type of presentation of the vestiges of our social dimension. They are almost like a romantic scene suggesting, additionally, a scenario of quietness where the city became a postcard. But at the same time, this sad beauty is the sign of the time dominated by the 'a-social' dimension of the pandemic. The city struggles with the effect of reciprocity interaction and its fundamental quality: the instrument to be present, to inhabit the world. In fact, the relation of individual/urban space is one of the primary meanings of the way to inhabit the world. The destruction of social relations with the spacing means, at the same time, the ruination of the urban social dimension with the lockdown factor that isolates people inside, thus developing an electronic social construction of reality.

The electronic space, lived in the sharing life of emotions, show us the potentiality of the digital windows creating a conceivable manner to stay together and animate the world. The outside without human beings seems something different. Many opinions put the accent on the possibility to appreciate the beauty of the urban landscape, the soundscape of the urban structure with the absence of noises, the flowering of nature. This makes us think about the place of humans. Today, many discourses arguments about 'how' to think the city of tomorrow with the resilience, the co-construction with nature or simply a more ecological city. But at the same time, we can perceive the intensity of technological control with drones, cameras, new apps and militarization generating contemporary anxiety by surveillance.

So, how to think the actual transformation and of social life through the urban space? (Re) think the urban space pay attention to dissimilar elements but, succinctly, suggest that the urban body is a part of us, an extension of the human body. The new settlement and frequent of the street are synonymous of an intensity to be together. The street is a magma, a social glue indicating societal energy that must never die. The importance of the street for the construction of social reality means to revoke the duality individual/urban space as an evident element of vitalism. Life is also synonymous of the street and urban sections where the Being is externalized as an ontological dimension. The open windows with the sound of music from inside that invade the street, for example, was one of the modalities or better a tactic, following the idea of the 'invention of daily life' in Michel de Certeau (1981). It marks a presence, to animate the outside and construct an emotional atmosphere shared with the others.

We know how emotions are important to the structure of daily life. Urbanity is also designed from this point because emotions participate in the creation of urban ambience as a sensorial impact on the human and urban spaces. The emotions can be considerate, through the senses of course, as an interface between the urbanity and the individuals configuring our environment and the way to be in this environment. Urbanity must be considered not only for the simple functions or materiality but it is necessary to put attention on the 'immateriality' i.e., the way we feel the urbanity. We can also talk about sensations, sentiments that allow a

perception of the city. It would compose an imaginary of emotional spaces shared by the individuals and, in this direction, we assist to particular manners to do, to be in the space considering also the porosity inside/outside.

The spatial dimension acquires new sensorial forms as consequences to the reconfiguration of the space to manage the pandemic situation. We can perceive in the urban panorama new signs and symbols that the individuals must recognize in its visual sensitivity as a kind of new alphabetization of spatial semiotic. The predominating of visibility is one of the keys of lectures to approach the urbanity and because it's one of the most stimulated senses and our eyes must decrypt many stimuli to read the city as a text. The various signs and symbols became a language for us and all the transformations change the inter-sensorial mode to be in the space developing as well the social reality in the urban configuration. In this phase, we can assist in a reorganisation of space through new codes to decipher and interpret. In this layout, we can say that there is a new alphabetisation because we must reorganize our visual perception. It is possible to apprehend a new symbolic language that redefines our urban social life in the optic to observe the relations between social comportment and urban forms. One can talk about altered architectonic affecting new categories of open and enclosed spaces where generate different settlements of distance.

THE NOTION OF PROXIMITY

Proximity is within a re-arrangement of presence where demarcations, limits, restrictions transform our spaces of 'contacts,' often generating a crisis of presence. In fact, one of the first appearances was to desert urban life with many places closed. It is impossible to be lived because the settlement was the non-contact and the inside private space was the 'safe' universe. The non-contact or more common the 'social distance,' influences and re-defined the practice of the social urban space. New sensorial orientations are also the significance of the practice that the individual must interiorise concerning the multiple marks on the ground. These marks proliferate actually in our cities on the sidewalk or inside the malls, schools, markets, shops, etc. The sensorial attitude is characterized by the signals directing our glance, signs and symbols of new social parameters to be in the space. They remind to manners to apply with the calculation of distance, use of masks, put the gel, wash your hands, etc. This is the visual symbolic panorama of the actual urban situation. Individuals are confronted to recognize some signs incarnate in the new dimension of architecture and urbanism. This also means a new perspective of the significance of something that changes our mental, corporal and emotional feeling within the city. An epochal question that arises in a complex dimension with a phenomenological topic where the city must answer with a proposition of mutations in conformity with the distinctive situation. In this condition, the urban and architectural factors are considered as an illustration of inhabited spaces. It has a direct impact on forms of perception of external and interior lived spaces because are a prolongation of the individual and the evident manifestation of social behaviours with a determinate influence on lived experience.

There is a relation between the natural space and the anthropized space that configures the social landscape. It's a typology of the aesthetical process of architecture and spatial dimensions as a predisposition to lived experience. It must assume a disposition to the

strategy of ‘transformability’ of the city and, consequently, human nature. Many questions and interrogations of possible changes and directions are stipulated where the urban and social dimensions must answer for a ‘better’ future! The problem is that we put many attentions on the future and we forget the present, the lived experience in the *hic et nunc* of our situation. The impression is that people need urban places to be present in the world. This is because there is a concatenation, a vitality of forms between human being and urban spaces. We see that the reaction of people after the confinement was the invasions of the street, the pleasure to be on terraces of bars, restaurants, coffees that means, simply, a manifestation of social life presence. The pandemic situation creates a kind of annihilation of urban atmosphere generating mutations of sensations. This does not mean that social vitalism is gone! But just a kind of an ‘adaptation to the situation,’ a famous theorem of William Isaac Thomas, where people ‘do with’ (as a strategy of daily life in Michel de Certeau theory and Michel Maffesoli idea of real). This ‘do with’ is also accommodation, adjustment, where people readapt its manners to respond to a social situation.

THE ECOLOGY RE-IMAGINED

The key can be to reinvent new codes where the space is hybrid with contamination and not just a simple function. It is similar to ‘open urbanism’ proposed by the reflection of Richard Sennet, in some recent interviews, with a flexible environment and the proposition of porosity to redefine the structure and manners. The problem is to think of a way to inhabit, the way we use the physical environment and how the behaviour can be adequate. One of the most recurrent opportunities to adapt the social life is the pregnancy of a green attitude. In our reflection, it would be better for the emphasis on the eco-sophical perspective to understand the pregnancy on the sensible and the collective way to inhabit. The ecosophy for the French philosopher Félix Guattari (2013) is an articulation between nature or environment, social relations and subjectivity. In our opinion, this synergy influences urbanity and the architecture and the way to live in the urban and social geography and represents a specific relation of an ontology of actual dimensions. Ontologically the need for ‘nature,’ also illustrated by the important contribution of the theory of Augustin Berque, is integrated into the connection that the human being has with its environment and *milieu*. It is an ‘onto-geographical’ relation (Berque, 2000) that redefines the attention of nature as the interaction between the individuals and space. The way we are interconnected to the urban social environment is also characterized by the way to feel through the sensible perception that generates a particular ambience. This produces a spatial experience and way to inhabit. The discussion about ‘green’ today is very common. Nevertheless, our intention isn’t an ideological reflection but a consideration of a relation with the contest where we live to re-build the social reality. The city, in this direction, represents a significant element to think about the aesthetic of ecosophical paradigm from the recreative forms to inhabit. This signifies a new creation of the sense of urbanology that put the attention on the knowledge of the city and its lived spaces. The ecosophy must be thanked, following the proposition of Maffesoli (2010) as a way to be in the world.

The idea of Guattari was also to think the hypothesis of ecology as a mode to re-invent new manners to be in the world and new forms of sociality. The ecosophical sensibility can

be a societal transformation with a particular highlighting on the relational ethic. This can be in consonance with the proposition of Arne Næss (2008) about a relational ontology where all the forms of life are interdependent. This interdependence can be based on some attention about architectural forms and the transformation of the inhabited landscape, where the technology has a big impact on the contribution of the mutations. The rhythm of actual urbanology is structured by the immersion in a relation between technique, culture and technology. Often the perception, when we think to the association urbanity and technology, is something similar to a dystopic sensation (i.e., a type of *black mirror* scenario¹). Technology is control of urban space and during the pandemic period, we have assisted to a 'dronization' of the territory. This fed the idea of an immersive control also structured by some apps of our smartphone and QR codes to verify the displacement of people in the epoch where we transform ourselves into simple data... Examples, among others, confirming a political strategy of control, an increase of surveillance as the progress of a new *Big Brother watching us!*

We don't have the intention to enter here in this argument that also generates many reactions about neo-liberalism and the asphyxia of terror provoked by the pandemic that struggles our social reality through the social distance and all the gestures we must apply. But we know that the human being needs contacts and, in this situation, new technology is also used to create forms of socialization (and in our opinion isn't a novelty), forming a digital society where the union between the Net and the lived spaces are a common fact. The city is more eco-systemic where the informatics architecture transforms the relation creating a rhizomatic experienced established on the connectivity. This generates hybridism of experiences and vital flux. In the optic of thought proposed by Massimo Di Felice (2010; 2012), we are in a biosphere defined like an 'info-material' where the individual is in interaction with nature through media prothesis creating an 'atopic connection.' For Di Felice, the informatics architecture based on the Net and with interactive and connective ecology produces another vision of the ecology that isn't a simple idea of the environment. On the contrary, it is a complex union of networks composing a new form to inhabit the world that we can call cohabitation. This generates at the same time a new version of a 'poetics of the space.' Poetic that the famous French philosopher Gaston Bachelard (1957) explained like a sensible phenomenology of the space and the instantaneity of lived experience. Urban spatiality is a coincidence with the existential spatiality.

In this direction, we must think that the interconnection of the physical environment with the social atmosphere and the human actions and the environment represent our surroundings. Well, it is obvious that one of the questions of our times is the requalification of the urbanity with special attention of the ecosophy and not simple ecology. A requalification that also concerns the life-style and the production of new spatiality where is possible to re-enchant the urban ecosystem. In this illustration, the biophilia seems to be a tendency of contemporary life. It represents a connection with nature and also a kind of well-being generating some specific configurations in an urban atmosphere. Our relation to nature products this 'biophilic city' where the cohabitation and the nature can be factors of social cohesion. In the optic of urban planning and metropolitan design, the empathy with nature is a topic that recreates the social urban space. The design conception of urban spaces, in fact, put the focus on biodiversity through the conception of spaces that sensitize the ecosophical values producing,

¹ The reference, of course, is to the British dystopian series *Black Mirror* created by Charlie Brooker.

in this way, a reciprocal relationship between human, nature and urbanity. We can also understand the vegetal design trying to engender well-being in urban dimensions as a strategy of social reconstruction of reality.

The vegetal design transforms our imaginary of nature creating a valorization of this effect and an urban emotionality linked to the ‘vegetalization’ of daily life experience. The idea of biophilia is one of the tendencies to regenerate our urban body. This can produce a straighten of social ties where space plays a vital role. The presence of nature, a strategy more and more current in the discussion of the city ‘post-covid,’ must be read like the creation of sensible ambience that influences the sensorial perception of the citizen and creates a kind of pleasantness. We can feel more and more in all the cities and for the human body, this necessity of green. In fact, one of the consequences of the lockdown was the escape from the metropolis and the refuge in green spaces outside from urbanity (that means in our opinion the danger to destruction the countryside). For this reason, some actual project – that we can also define as a projection of a sci-fi imaginary –, concentrates the attention on the ‘post-covid city’ as the eco-district thanked in the perspective of a self-sufficient city.

For instance, we can refer to the project in China by the Spanish architect Vicente Guallart. Its proposition of ‘self-sufficient city’ is a response to the climate catastrophe and to the covid crisis. It can generate new forms of architecture and lifestyle with the integration of porosity. This is also the idea of the theorization of the concept ‘the 15-minute city’ idealized by Carlos Moreno, one of the pioneers of the ‘Smart City,’ as an urban design approach to ameliorate the quality of life. This is done by creating cities where all the residents can reach everything they need within 15 minutes by bike, public transports, walk. A ‘no-car city’ we could say, following the dream of the current Paris Mayor Anne Hidalgo that is one of the most enthusiastic supporters of this kind of city in her proposition to transform the *City of Light*. For Moreno (2020), the object is the city of proximity with a massive network of places redefining the lifetime, a redefinition of the idea of city form that must overlook the ‘world-city.’ We must understand the mutations and risks of climatic change, new pandemic and the extreme forms of neo-liberalism and savage capitalism that smashed the social reality.

The project of Guallart and the idea of Moreno are conceptions of the mutation provoked by the actual crisis. They offer a proposition of a lifetime harmony where, again, the porosity as an extension is one of the keys. There are also many other suggestions where the individual has a central place and can contribute. We think to the ‘makers’ for example, to the reconfiguration of urban social life. For us, the mutation is also an occasion to humanize spaces through nature, reintegrate green strategies. The mutation is not just some interesting ideas and actualization of interventions (green architecture, shared gardens, vegetal wall...) but rather ontological and paradigmatic. This means rethinking the urbanity from ‘natural green’ creation as integration in the life-style. This also adds a poetic and sensible dimension as the complement of the re-signification of urban social life as a possibility to think all this arrangement as facilitation of eco-systems in an organic city to think like a body with its flesh, skin, organs. This is, at the same time, a mode to actualize the transformation of urbanity and the renewal of the urban panorama where the vegetation of lived spaces became a style that proliferates.

This must be imagined as an answer to the nervous intensification of life that showed Georg Simmel (1903) as the effect on the metropolitan cities. The ecosophy of the urban space, following the thought of Simmel, can be a way to forge the psychology of the urban and the way to think. For this reason, all the ‘natural’ conception are emblems of an eco-

societal stabilisation of actual metropolis with the scope to transmute the manners to live-together.

We can propose the idea of an ‘organi-city’ like an inclination to the modes to edify the human and urban habitat by the sensible mutation of the ambience. It offers a social harmony between human and environment where, for the ecosophical perspective, the man and the world are aspects of the same reality. And in this reality often we listen to discussions about the concept very common and popular like the resilience with the proposition of a ‘resilient city’ as a strategy of urban regeneration. This that signifies adequacy to the spirit of the time to develop the community capacity of a way to inhabit-together as a mode to be in the world; adaptation of a new form of urban life with an emergency of socio-aesthetical solidarity. But the ‘resilient city’ is often thanked as models of planning of risks and vulnerability of society. This is more ‘collapsological’ (another popular concept that invades our daily life with the proliferation of opinions and catastrophic analysis).

In our intention, associating to resilience the *reliance* (a way to be linked), we try to think to a process where the *homo urbanus* is connected to the *milieu* in its organic experience where the actions are a synergy of eco-social-urban well-being. In this sensibility, we can feel the tonality with spaces through sensible experience where the individuals adapt the way to be with the environment. Being in tonality in a sensible and effective way is a reflection about the importance of ambience. It also reflects the *Stimmung* that in Heidegger *Sein und Zeit* is a way to have access to being there, a manifestation of being revealing a *das Gestimmte* that means ‘to be-intoned.’ The intonation is a harmonic disposition that, in a reflection about the actual reality of the city, can be in relation to nature, to the ecosophical essence.

CONCLUSION

After further discussion, the present chapter holds that we are affected by the space and this is usually to the entire situation even in the pandemic period where people must have a new attitude that with time became incorporate in our sensorial modus. And the effect to be ‘affected by’ is essential to understand the way we react to singular situations. It also allows proving that the relationship that we have with the surrounding environment is effectual in a typology of ‘fleshly space’ that in the logic of ambience theory we can perceive from the sensible point of view that unites us to the urbanity. The urban space isn’t conceived as an anthropocentric dimension but, instead, through the re-valorization of daily life in congruence with the living space. We can also talk about the effect of topophilia that the geographer Yi-Fu Tuan (1974) illustrated as the perception of the environment that concerns the place with which the individuals have an affection relation and feel to be linked. To be attached is one of the keys to understanding the potentiality of the urbanity because the human being needs an intimate relationship with the city and environment that create, at the same time, the condition to be related with the others.

Also, within the effects of the pandemic situation, where many discourses are centred on a catastrophic point of view that announces (again) the ‘death of the city’ and social relation, the city endures being the sensible container of the lived experience of which the Being needs just to be in the world. The Being adapts itself to all kinds of situations and the street, the places, the spaces are a prothesis of ourselves; the condition of reality shows us that the

sociality is the way to support the world. Then, sociality is the hope to redefine the construction of reality also with the consideration of the importance of digital dimensions. The interconnection with a new arrangement of the interior spaces that are more than more windows open on the world. In substance, the city must be perceived as a body. This requires a change of paradigm that finished with the obsessive vision of functionalist planning and achieve the perception of the organic city with all its pores that exude the vitality and made manifest the urban epidermis. 'This is the way, step inside'²....

Chapter 496

PANDEMIC, SOCIAL POLICIES AND EMOTIONS IN THE METROPOLITAN AREA OF BUENOS AIRES

Angélica De Sena*
CONICET-UNLAM-UBA

... as is often the case, observing current events illustrates the understanding of the past and delving into what has happened clarifies what is happening: many of the Interdependence mechanisms of our days continue the changes of the past ... (Elias, 1993).

ABSTRACT

The Metropolitan Area of Buenos Aires is one of the poorest areas of Argentina. In this area is located La Matanza, the largest geographic municipality with the largest population and greatest vulnerability, as indicated by data from a pre-pandemic investigation. In March 2020, in Argentina the “social, preventive and mandatory isolation” was declared in the face of the Covid-19 pandemic, which meant an increase in poverty and social assistance. In this context, an online survey study was carried out (in four waves: April, May, June and September/October) in order to ascertain the changes in the poverty situation of the population of La Matanza among the people receiving a social benefit, and related emotions around the pandemic and their own situation of vulnerability. For this, the exposition of the article will be: a) a review of the social and economic situation of the territory in question pre-pandemic; b) development of the theoretical perspective regarding social policies to address poverty in connection with emotions, considering social interventions that construct meanings, elaborate perceptions, and are located in the performativity of the aforementioned policies; c) development of the methodological aspects of research and analysis of quantitative information, taking into account the population that receives a social program and the emotions that emerge in relation to the pandemic. In this way, this chapter aims to make a substantial contribution to understanding the impact on the sensitivities of the recipients of the social interventions implemented in the context of a pandemic.

Keywords: pandemic, social politics, emotions, La Matanza, poverty

REVIEW OF THE PRE-PANDEMIC SOCIAL QUESTION IN THE TERRITORY OF LA MATANZA

Greater Buenos Aires is an area that surrounds the City of Buenos Aires, made up of 24 districts¹; which as a whole form an “urban area,” since they make up the largest urban complex in the country. According to the last census of 2010 (INDEC), the city concentrates almost 25% of the country’s inhabitants. This region not only represents the largest single segment of the population, but is also where the highest levels of poverty and indigence are concentrated. In 2019, poverty affected 39.84% of the people who live in this area, and in the first quarter of 2020, with the start of quarantine due to the COVID-19 pandemic, it reached 47.5% (INDEC). The municipality of La Matanza, located in this region, is characterized not only by being the most populated - in 2010 it reached 1,772,130 people in a total of 483,397 homes (INDEC)- and extensive with 325.71 kilometers squares, but because it has a deep spatial segmentation that, in principle, can be subdivided into three large areas that are very different in terms of their socio-housing, economic and cultural characteristics. The first of these areas is that bordering the Autonomous City of Buenos Aires, where the inhabitants have more possibility of accessing drinking water and sewer services, it has most of the paved streets. The presence of villages and settlements is focused on relatively small sectors since they present to a lesser extent in comparison to the following areas. It is the area with the highest tax collection and the lowest rates of poverty and indigence due to the fact that it is the area that has achieved the greatest development over the years. The second zone has an intermediate population density. Only in recent years was the coverage of drinking water and sewers expanded, only half of the streets are paved and tax collection is irregular and/or poor. The third area is the one with the greatest vulnerability, where there are the greatest infrastructural and social deficits, the possibility of accessibility to services, educational and health centers decrease compared to the other areas, with the highest poverty index and the one furthest from the City Buenos Aires. Precarious employment and housing conditions deepened in the 1990s and have spread, with alterations, to date, generating new configurations in existing social networks. The district stands out for the development of grassroots organizations and social movements that emerge as a strategy to achieve occupation processes and popular settlements (Manzano, 2007; Barna, 2014).

In order to establish a map of the situation of social and economic vulnerability of the district, a description of the habitation conditions will be presented, considering the overcrowding conditions, access to services, working conditions and reception of social programs, ending with the elaboration of an index regarding the basic living conditions of the homes of La Matanza.

¹ It is necessary to consider that the National Institute of Statistics and Censuses (INDEC) mentions 24 districts in the official website of the Autonomous City of Buenos Aires (<https://www.buenosaires.gob.ar/gobierno/unidades%20de%20proyectos%20especiales%20y%20puerto/que-es-amba>) are indicated 40 and, the CIPPEC 31. These distinctions run the limit towards municipalities traditionally considered of rural type, called “inland.”

Following the results of our investigations² prior to the pandemic, we have identified that the district presents a deep segmentation and spatial segregation among the three aforementioned zones (PELM, 2005, De Sena et al. 2020). Regarding the issue of habitation, 122 informal settlements were identified (TECHO, 2016)³, mostly in the second and third zones. It is in this sense that we have found that the population in the worst socio-economic situation, the one located in zones two and three, is the one that must buy water for cooking, and the one that has least access to sewers, with only 3.1% of homes in zone three having such access. In this framework, it is noted that 8% of the homes are in critical overcrowding conditions.⁴

La Matanza is a district of humid areas, bathed by a large number of streams and the Matanza-Riachuelo river. These streams and waterways cross large areas, which generate floods and contamination⁵, so living nearby can mean damage to homes and human health. We have observed that in a third of La Matanza the neighborhoods have a stream nearby. This is more serious in the second and third zones where almost half of the neighborhoods have a nearby stream. In this sense, the news regarding floods are frequent. We have detected that 43.6% of the lands are flooded. This information is completed with two more elements: the existence of storm drains in the neighborhood and the type of streets (paved or dirt). The storm drains serve to collect the water derived from the rains and prevent floods from occurring. In this municipality, a third of the neighborhoods do not have storm drains, a situation that worsens in the second zone - 58.3% do not have it - and in the third, 57.1% do not have it. This set of factors begins to explain the floods, but the public health problems they cause also deserve attention (De Sena et al. 2020). Along with this, the industrial discharge without previous treatment, and the clandestine dumping of garbage, is not only a constant factor of contamination of the Matanza river, but also of the water courses of the tributary streams in the district, especially Arroyo Morales, the longest within the district's territory (PELM 2005).

Regarding the employment situation, it was identified that 52% of the working population does so in informal conditions and most of the occupations refer to semi-skilled and unskilled activities. It is possible to observe some differences by gender. For example, a third of women perform cleaning tasks, and 14.1% of men are street vendors or laborers. And the situation is always more unfavorable for the second and third zones (De Sena, 2019).

Regarding the means of income that the household has, we have observed that 16% lack a regular monthly income, and that they subsist on exceptional income or due to debt, evidencing the precarious situation in which life develops.

Regarding the socio-economic level⁶, where ABC1 refers to the high level, with better economic and social position, the medium-high and medium-low level C2 and C3

² We refer to the quantitative and qualitative project: "Main features of the" social question "at the beginning of the XXI century. La Matanza 2017-2019." (PROINCE) PIDC code 55 B 206. National University of La Matanza. 2017-2018; under the direction of Angélica De Sena. The data presented here respond to a household survey witnessed, with a probabilistic sample of 829 households throughout the municipality of La Matanza.

³ <http://relevamiento.techo.org.ar/index.html>.

⁴ Critical overcrowding: corresponds to households with more than three people per room. For the calculation here, three or more people were taken to determine overcrowding.

⁵ <http://www.acumar.gob.ar/caracteristicas-cuenca-matanza-riachuelo/>.

⁶ This was taken as a base model NSE simplified (Socio-economic Level) questionnaire, corresponding to the year 2015 (latest version), of the Argentine Society of Marketing and Opinion Researchers (SAIMO). For this, the following variables were considered: income (considering the values of the total basic basket according to INDEC); medical coverage; level of studies achieved; working condition; and type of work activity.

respectively, and the low level divided into D and E refers to the low-high and low-low respectively. In La Matanza, the results indicate that 69.6% of the homes are of low socioeconomic level, and only 1.2% reach the high level and 23.7% the medium level. When reviewing the socio-economic level according to the area where the home is located, it is observed that the small percentage that achieves the ABC1 level is essentially located in the first area. While it is relevant to note that level E, in the first zone reaches 25.1%, in the second 39.4%, reaching 48.2% in the third. In other words, although the population in general is of a low socio-economic level (almost 70%), almost half belongs to the third zone.

Finally, and with the aim of broadening the view, we elaborated an index that would allow us to determine living conditions in a multidimensional way. Understanding by “basic living conditions” of a person the ways in which they develop their individual and social existence, linked to economic, health, education, employment and habitat aspects. Based on this, the following dimensions were designed: a) employment, whose indicators refer to the condition of activity and quality of employment; b) economic sustainability, in this case the indicators are related to the origin of the household income (work, social programs) and the receipt of different products (food, medicines, etc.); c) access to health, which refers to having some type of medical coverage and accessibility as distance from the health center or hospital⁷; d) education, taking into account the educational level of the respondent and the schooling of boys and girls in the home; e) housing, the level of overcrowding and access to health services were considered as indicators; and f) the environment of the home, in this case the indicators are related to the neighborhood conditions (garbage collection, flooding streets, storm drains, and nearby public transportation, among others). Based on this, the results obtained indicate that only 58% of households have basic living conditions; of the remainder, 3.1% do not possess these, and 39% only partially have them. This situation worsens in the second and third zones, where only 47.8% and 44.1% respectively have basic living conditions.

It is in this context that we identify that in 26.2% of the households at least one person receives a social program to address poverty, and in these households the index showed lower results. Among households where there is a social program, only 22.9% have basic living conditions, while where there are none, almost 70% have such conditions.

The data presented so far show that the entire municipality of La Matanza prior to the Covid-19 pandemic was clearly exposed to deficient social and economic conditions. This situation is even more serious among people who receive a social program to address poverty⁸. In this context of high vulnerability, with a high percentage of people living from informal jobs⁹ and with social programs, that is why we wonder about the impact of the Covid-19 quarantine and the emotions associated with it in this population.

⁷ This is a relevant indicator considering the geographical distances of the municipality and the inequalities between the first, second and third zones.

⁸ 76% receive a cash transfer and they are women (Dettano, 2020).

⁹ The informal workers mentioned must be added to the recipients of social programs who, in order to improve their income (given that according to our inquiries the subsidy only occupies the place of a “help”) perform roles such as domestic workers, street vendors or other unskilled activities (Dettano, 2020).

Table 1. Basic living conditions according to whether or not they have received programs to alleviate poverty, from the Matanza district, in percentages

Basic living conditions	General population	Households with at least one person receiving a SP	Households without receiving a SP
Has	54.9 %	22.9%	69.4%
Partially has	39%	65.6%	30.2%
Does not have	3.1%	11.5%	0.4%
Total	100 (829)	100 (216)	100 (613)

Source: Own elaboration.

In the next section, a review of the theoretical perspective regarding social policies to address poverty in connection with emotions will be carried out, considering social interventions that build meanings, elaborate perceptions, considering the performativity of the aforementioned policies.

EMOTIONS, SOCIAL POLICIES AND POVERTY

The social question approached as an aporia between formal equality and inequality of the Modern State (Castel, 1997) or as the contradictions of the Welfare State in capitalism (Offe, 1990), is associated with the social policies as interventions from the State towards the population in order to tend towards the *welfare* of the population and/or to suture market failures.

The question regarding what social policies are has been widely problematized from different disciplinary spaces - essentially the economic and social - and linked to the Welfare State, considering the strong presence of the State in people's daily lives since it is the one who assigns and redistributes the resources. Therefore, social policies will affect the production and reproduction of life and therefore in the construction of our daily lives, whether they aim to ensure certain minimum levels and certain opportunities to all members of the community (Hegenbuch, 1958 , in Titmuss, 1981), or as an attempt to direct the life of society along a path that it would not follow if it were allowed to run its course (Lafitte 1962, in Titmuss, 1981), or as state actions that contribute to the reduction of social conflicts ensuring the temporary persistence of the capitalist accumulation regime (Fleury Teixeira, 1997; Faleiros, 2004; De Sena and Cena, 2014). In other words, beyond the definition of what we call social policies, these always refer to State interventions for specific purposes, which respond to the ideological conceptions of a given government, which intervene in the life of the community. Therefore, both the actions and the omissions of each social policy construct meanings and shape individual and social subjects, from which a social fabric is built and socialities are consolidated. In this way, if they are interventions that shape the conditions of production and reproduction of the life of the different sectors and social groups, then they condense the possibilities of naming meaning and doing (De Sena, 2016). We have already mentioned in other places that social policies have a normative character, that they also establish meanings, ways of seeing and feeling the world that perform the social question and structure emotions in the bodies of millions of subjects, as recipients, designers, and

implementers of social policies (De Sena, 2016, De Sena and Scribano, 2020, Cena 2015, Dettano, 2017, Cena & Chahbenderian, 2012, Sordini, 2020, among others). For this reason, the sociological analysis of social policies from the perspective of bodies/emotions contributes to the study and understanding of the structuring mechanisms in contemporary capitalism. This is based on trying to combine a vision of these policies and how they build and consolidate ways of being, doing, thinking, and feeling, that structure the bodies and emotions in the subjects. There are intersections and articulations between the redefinitions of the “social question,” the elaboration of social policies within the framework of the processes of state regulation of the conflicts between capital and labor, the necessary and desired sensitivities for this to happen, and the interventions of the agencies that are involved.

This means that social policies have a central place in defining the characteristics that the process of social production and reproduction will have in a given historical context, generating the conditions for it and for developing sociability. Therefore, these policies also operate in the symbolic aspects of life and in those associated with the cognitive-affective. In doing so, they institute and reproduce (causing, imposing, canceling and/or repressing) certain images, models and stereotypes of society, the subject, women, work, family, motherhood, among others, and emotions: anger, happiness, love, anger, fear. This configures the structure of sensitivities (De Sena, 2014, Scribano and De Sena, 2013) that affect the daily ways of living and the vicissitudes of the intervened subjects (Scribano, 2010).

The feelings and emotions experienced by the agents, as cognitive-affective practices, have an intertextuality linked to a specific historical and social context that corresponds to specific social situations (Luna Zamora, 2007, Scribano, 2007). “There is a necessary link between affective subjectivity and objective social situation” (Bericat Alastuey, 2000: 152) from where a set of emotions are induced in the actors, but also where controls that affect their feelings are incorporated. These norms are barely perceptible when *we feel what we should feel*, and we learn to manage the emotions corresponding to each moment, towards better social regulation (Scribano, 2007, 2012).

Therefore, the approach to the social question materialized in social policies It not only promotes or restricts certain emotions, but also the social implications of such affectation, that is, how to build the daily life from conditions of deficiencies, what will be the ideal “emotional competencies” to reverse them, to print them or to get used to them (Luna Zamora, 2007; Hochschild 2011). Therefore, reviewing the emotions in the populations intervened through social programs leads us to understand the modes of social structuring. From these positions, in the following section, four surveys carried out during the quarantine by Covid-19 in the population receiving poverty care programs will be analyzed in order to uncover their emotions, as indicators that will allow us to later understand their practices.

EMOTIONS, SOCIAL PROGRAMS, QUARANTINE AND COVID-19

In this section we will analyze a series of results obtained from an investigation¹⁰ that was carried out at the UNLaM in order to make visible some behaviors of the population of

¹⁰ Project “The social question in the party of La Matanza in the context of a pandemic.” Vincular 2020 Program. UNLaM Rectoral Resolution No. 218/20. Secretariat of Science and Technology. National University of La Matanza. Director Angélica De Sena.

La Matanza against the restrictions established by the quarantine established in response to Covid-19. It was carried out through an online survey across four moments, the first from April 4 to 11, the second in May, the third in June, and the last at the end of September and the first days of October, from a non-probabilistic sample, based on a self-administered questionnaire with 3,291 respondents. The distribution ranged from the “snowball” technique to people over 18 years of age residing in the La Matanza district as part of the Greater Buenos Aires region. In this discussion, we will take as the focus of analysis the surveys completed by the people who receive a social program aimed at the alleviation of poverty (a total of 504 cases).

The year 2020 will be marked by Covid-19, with the first confirmed case in Argentina appearing on March 5, after which the number of infections increased rapidly, and on March 11 the World Health Organization declared the coronavirus outbreak to be a pandemic. In this context, and for the purpose of preventing the health system from collapse, on March 20 the Argentine national authorities established Social, Preventive and Mandatory Isolation (ASPO) in decree 297/2020¹¹, known as “quarantine.” The isolation was maintained -with some openings- until November 7, 2020,¹² the date on which the start of the stage of the “Social, Preventive and Obligatory Distancing” (DISPO) was announced¹³ in the Autonomous City of Buenos Aires and Greater Buenos Aires Ulna (GBA), the area where the greatest number of cases and the longest period of isolation were concentrated. The ASPO decree limited the possibilities of mobility and travel along routes, roads and public spaces, and only tasks considered as *essential* could be carried out. So the cities were “closed,” the streets were emptied, and we all had to “stay at home” in the face of ignorance of the behavior of the virus. One certain reality was the high level of contagion, and the only known means of prevention was a strategy of “isolation,” a method that is not new and has been used in other pandemics over the years, such as the ‘Spanish flu’ of 1918.

This meant the closure of all face-to-face activities and only those related to food, hygiene and health were enabled. The rest compulsively entered virtuality. The advice that had to be followed were: “stay home,” “wash your hands,” “disinfect surfaces,” and “keep distance between people.” These councils were operationalized in a different way in the population, in relation to their social, labor, and accessibility conditions prior to the pandemic.

In the previous point we made mention of emotions as the result of the structuring and organization of life processes, tied to the different and multiple modes of State intervention, and particularly towards this population that receives interventions from a social program given their situation of poverty.

Elias (1993) refers to the relationship between the control of the subject in relation to emotional structures and how these are different according to social classes. Said control is made effective through the regulation of individual emotions by means of internal or external coercion and - in some way - the structures of human manifestations. In this way, external coercion becomes internal and the different emotions (shame, fear, etc.) are structured as a certain continuous *self-control*, as unplanned configurations but in a specific order. Scribano (2009, Scribano and Vergara, 2009) refers to the mechanisms of social supportability and the

¹¹ See <https://www.boletinoficial.gob.ar/detalleAviso/primera/227042/20200320>.

¹² Therefore, the surveys were carried out in different months.

¹³ According to Decree 875/2020, DECNU-2020-875-APN-PTE. Official Gazette <https://www.boletinoficial.gob.ar/detalleAviso/primera/237062/20201107>.

devices for regulating sensations as a way of living life for those who are part of the world of No (no health, no education, no housing, etc.), but that in Argentina for some decades these have *not* been replaced with a massive array of social programs (De Sena, 2011).

Elías (1993) argued that emotions are made up of three major components, namely the somatic, behavior and feeling. For this reason, subjects faced with situations of uncertainty or danger prepare to face them by fighting or fleeing; it is in this sense that Scribano (2012) affirms that body/emotion are inseparable elements. In this way, it stresses those biologicistic positions, constructionists or naturalists, with an approach that understands them as a result of social structuring processes. Hence, for Luna Zamora, emotions can be conceptualized as “learned schemes, reinterpreted, negotiated and functionalized or refunctionalized to structured and structuring sociocultural contexts (...) attention must be paid to the preconditions and structures that determine the experiences of certain emotions or other individuals who interact under these premises, defining and getting involved based on them” (Luna Zamora, 2005: 29). For this reason, although experienced individually, they are recognized by others in daily life and the State, based on the diverse and profuse modes of intervention, and this is constituted in the elaborator of a cognitive-affective text, in which social policies become the organizers of everyday life.

The ways in which modern states work, the configuration of societies, and the different institutions, all impact the moods of populations. The State configures a mode of sociability, which accentuates aspects such as joy, vivacity, happiness, cordiality, and kindness; inscribed in each historical context that grants a type of life experience, it elaborates a mode of interaction and exchanges (Simmel, 1939).

For this reason, we question ourselves about the behavior of the population that, as shown in point 1, find themselves in a situation of social vulnerability. The pre-pandemic economy was complex, with respect to the emotions associated with Covid-19.

In the pre-pandemic investigation, we investigated the people who receive a social program, and there are two indicators that we present here. The first question regards how it feels to receive a social program, and the highest percentage responses are: 22.6% that it is a “help”¹⁴, 13.9% that it is a “relief,” 8.7% “joy” and 7.8% “Anger, anger.” In other words, in one way or another, the different ways of accounting for the emotions around the program refer to a further contribution to the family economy.¹⁵ The next question refers to how they feel each day, to which the most frequent responses were: 20.7% mentioned feeling “joy,” while 15.6% felt “sadness, pain or suffering.” These are followed by 10.8% with “anger,” 7.4% feel “good,” 6.6% “tired” and 4.9% “happiness.” In this way, we can observe that in everyday life in limited conditions, both contextual and individual, only a quarter (joy + happy) of the population mentions emotions related to *well-being*.

In this context, the quarantine restricts people’s possibilities for carrying out their work activities, especially considering that they were informal, further limiting their meager income. This is so much so that 62.8% respond that their economic situation is worse after quarantine since their income is lower. This situation is more serious according to the area of

¹⁴ In this regard, see Scribano Adrian and Angélica De Sena (2018) “Aid as the central axis of policies for the sensitivity of conditional income transfers,” in De Sena, A. (editor). *Social intervention at the beginning of the XXI century: conditional transfers in the global order*. ESEditor. Buenos Aires. Pp 253-284. Available in <http://estudiossociologicos.org/portal/la-intervencion-social-en-el-inicio-del-siglo-xxi-transferencia-condicionadas-en-el-orden-global/>.

¹⁵ It is necessary to consider that most of the programs refer to a Cash transfer.

residence. That is to say, although the situation is always bad - in line with what was mentioned in point 1- in the first zone for 56.5% their income decreased, in the second zone this was the case for 62.7%, and in the third for 69.2%. The economic situation worsened from the age of 40, among the ages of greatest work activity between 25 and 64 years, and among women. The income of this population was decreasing with the quarantine and associated with it the impossibility of carrying out the work activities in which they were previously engaged; but the high level of inflation in the Argentine economy must also be added.¹⁶ It is in this context that it should be analyzed that only 37.5% of the population mentioned that “they do not leave their home,” making it clear that the rest do, and possibly for some task related to improving their day-to-day life. This behavior was modified with the months of quarantine and the worsening of the economic situation for people who receive social programs.

	April	May	June	September	October
<i>Your income is lower than before the quarantine</i>	52.4%	83.3%	72%	71.4%	73.3%
<i>Today your economic situation is worse than before the quarantine</i>	57.7%	58.3%	66.7%	67.1%	76.7%

When asked why sustaining household expenses from quarantine only 5.9% can sustain all household expenses, while 54.5% can only sustain basic household expenses and 39.6% cannot even sustain expenses basic.

It is in this context that we will try to review the emotions of this population in relation to the first three months of quarantine (April, May and June) and then those of September/October, given that at that time, although the decree of isolation was still in force, according to our notes¹⁷ field, the isolation was no longer fulfilled and the streets were already populated with people circulating.

We will first analyze the initial moment of the quarantine (surveys of April, May, June¹⁸). At this time, among the recipients of poverty care programs, the emotion that arises in the first months of quarantine is fear with 48.8%, followed by anxiety with 26.5% and concern with a residual percentage of 1.2%¹⁹.

But these emotions change as the days pass and the quarantine continues: fear decreases since the month of April when it reached 53.3%, and in the month of May it drops to 45.7%, and in June it falls further to 37.3%. Conversely with anxiety: in April it is 23.6%, in May it is 30% and in June it rises to 32.2%. A quick explanation is that people are getting used to living with the virus, but also have to carry the anxiety that living with it means.

In order to better understand these two emotions, we will review them with two indicators that bring us quite close to the living conditions of this population: one refers to the area of residence (first, second and third) and the other to the level of education achieved.

¹⁶ Inflation in Argentina is a long-standing problem, in 2019 it reached 53%. For 2020, inflation in April and May was 1.5% respectively, in June 2.2%, September 2.8%, and October 3.8%. The largest price increases are in food products (INDEC, 2020).

¹⁷ Information emerged from the research team that resides in La Matanza.

¹⁸ We refer to 329 cases.

¹⁹ Although in this writing we refer only to the recipients of programs of attention to poverty in the face of Covid-19, we highlight that this relationship is inverse among non-recipients, with 35.5% feeling anxiety and 28.9% feeling fear.

Regarding the area of residence, in the first area (the most affluent) fear reaches 35.6%, in the second area 51.7% and in the third 53%, that is to say, when conditions are worse fear increases. Regarding anxiety in the first zone it reaches 35.6%, in the second to 20.2% and in the third to 25.9%; then this emotion is felt mostly in more favored socioeconomic areas.

Zone of residence	First Zone	Second Zone	Third Zone
Fear	35.6%	51.7%	53%
Anxiety	35.6%	20.2%	25.9%

Regarding the level of educational achievement in relation to fear of Covid-19: 57% had a low level of educational attainment²⁰, 43.1% had completed intermediary studies, and 35% had a high level of education. On the other hand, anxiety appears for 21.1% of those who had only reached a low level of education, it increases to 29.7% for those with intermediate levels of attainment, and 40% for those who have completed higher education. In this way, it is observed that lower levels of formal education increase fear, and vice versa with respect to anxiety.

Studies achieved	Low	Medium	High
Fear	57%	43.1%	35%
Anxiety	21.1%	29.7%	40%

What has been said so far allows us to hypothesize that fear increases as living conditions are worse and anxiety is less.

To continue with our analysis, we will consider the emotions that arise in this population after completing the 6 months of isolation decreed by the national government. Although according to our studies of the population, compliance with isolation was in fact limited. In this period emotions not mentioned above arise. Thus, the emotions most mentioned in the face of Covid-19 by people²¹ who receive a poverty care program are: fear amongst 25.1%, boredom amongst 18.3%, anxiety amongst 17.1% and worry amongst 15.4%. Concern previously was at only 1.25%, and with the continuity of the increase in cases and the permanence of the ASPO it increases. And, an emotion not mentioned above also appears such as boredom.

When analyzing according to the area of residence of the respondents, the same relationship is maintained as in previous months: in the first area, a lower percentage than in the third and the same as in the second. Concern tends to be less in more disadvantaged areas since in the first it reaches 20%, 11.5% in the second and 14.3% in the third.

	First Zone	Second Zone	Third Zone
Fear	23.1%	23%	30.6%
Boredom	15.4%	24.6%	14.3%
Anxiety	16.9%	16.4%	18.4%
Concern	20%	11.5%	14.3%

²⁰ Low refers to those who reached primary schooling, medium those who managed to finish middle school, and high those with university studies.

²¹ In this case we refer to 175 cases.

Continuing with the same criteria, educational attainment was also considered. This indicator seems to have a behavior similar to that of previous months. Fear continues to be greater as the education achieved decreases (36.34% for low studies, 26.7% medium and 12.1% high). Anxiety is greater for those who have completed higher level studies (9.1% low studies, 16.7% medium, and 24.2% high). Concern also increased with education, reaching 21.2% in those with higher education and 13.6% for those with a low level of education. Meanwhile, boredom goes down with educational attainment, given that 27.3% of those reporting this emotion have low levels of education, 18.3% medium and 12.1% high.

Studies achieved	Low	Medium	High
Fear	36.4%	26.7%	12.1%
Boredom	27.3%	18.3%	12.1%
Anxiety	9.1%	16.7%	24.2%
Concern	13.6%	14.2%	21.2%

One more element to take into account is that 67% of the population who mention feeling afraid are aged between 25 and 44 years old. It is women (35.6%) who feel fear more than men (20.4%), while anxiety is almost the same between genders.

And finally, regarding the economic issue, among those who evaluate their economic situation worse than before the quarantine, 31.4% feel fear and 32.6% anxiety. Among the beneficiaries of programs who consider that their situation is better than before quarantine, 16.7% feel fear and 22.4% feel anxiety.

Economic situation	Worse than before quarantine	Same as before quarantine	Better than before quarantine
Fear	31.4%	34.9%	16.7%
Anxiety	32.6%	25.7%	22.4%

Fear is an emotion that has been identified prior to the appearance of Covid-19, in the narratives of this population associated with the social program as a triple structuring linked to chance, the government, and the instability of both access and continuity to these policies of attention to the situation of poverty (Cena, 2019).

Feeling fear constitutes an emotion intimately linked to everyday life. In terms of Koury's study (2017) of fears in the city, this emotion impacts the organization of daily life, directly or indirectly affecting the practices of populations. Complementarily, Luna Zamora (2005) maintains that fear is constituted in and from an emotional experience, the product of the interaction between individual agency, biology, biography and society.

Continuing with Elias (1993), violence and fear are two strong elements in the processes of historical changes and, as a counterpart, trust and tolerance, the latter two were not mentioned even once by the respondents. The quarantine established through a decree told us what it is allowed to do and what is not allowed, leaving room for the configuration of behaviors and their regulation; a new organization of fears.

... "the structure of fears is nothing more than a psychic response to the constraints that men exert on others within social interdependence. Fears constitute one of the ways of union -and the most important- through which the structure of society flows over individual psychic functions. The engine of this civilizational transformation of the behavior of the social constraints that operate on the individual, such as fears, is constituted by a complete modification of the social constraints that operate on the individual, by a specific

change of the entire relational network, and above all, a change in the organization of violence” (Elias, 1993: 527-528).

The author refers to fear as a powerful element in the process of civilization towards the achievement of social prohibitions. These prohibitions rest on a “natural and historical” fear, but it is never natural but responds to history and the structure of social relations. Fear, then, serves as a mechanism of *social support* based on self-control and as a barrier to any conflict.

On the other hand, fear for some authors has a common thread with anxiety, although others try to separate it (Sierra, Ortega & Zubeidat, 2003). Anxiety appears linked to a forward action, this agitation or anxiety also leads to a state that does not allow calm. Anxiety appears on the one hand as an adaptive response, and on the other with a certain link to fear, although Marks (1986) differentiates it by linking it with some anticipation of future or unpredictable dangers, and as a consequence of capitalist structures of pessimism towards the future (Woods and Grant, 2006).

In this way we can continue to hypothesize that fear and anxiety are in relation to the material conditions of life, so that when these conditions are worse fear and anxiety are also. In other words, the strong interdependence between what Elias (1993) calls the “inner world” and the “outer world,” forming interdependence networks, giving way to what the author calls the self-control apparatus.

According to Sauri (1984), fear is a ritual and symbolic process (not basic) whose purpose is to reduce anxiety in the face of uncertainty, as regulatory mechanisms, in some cases it can be lurking until it leads to an extreme degree of terror or panic. When this happens, the subject abandons direct confrontation and starts to flee or becomes paralyzed (Saurí, 1984). Meanwhile, for Bauman (2008), “fear” deepens when it is dispersed, unclear and cannot be identified with a specific object or place and considers it responsible for the continuous state of fear of (liquid modernity). Finally, Geoffrey R. Skoll (2010) points out fear as functional to the interests of an elite that intends to extend its hegemony and for this, “global fear” is fundamental. From discourses of fear as a restrictive, but at the same time stimulating, political being, as a result of a capitalist state where many have little and most of the wealth produced is little distributed. In this state of constant conflict, fear works as a deterrent mechanism so that citizen demands are dispersed or at least cannot be organized as a coherent whole.

CONCLUSION

A few brief lines to reflect on Covid-19 and the modes of social regulation. The 21st century was embedded in a resounding way in our lives, illuminating to the point of being dazzling the precarious situations in which populations lived accustomed to lack. In this case in La Matanza as a sample of a Greater Buenos Aires, once a symbol of industrialization and now as a constant unease, vulnerabilities and precariousness: in education, in the type of work activity, socioeconomic level, access to housing, access to infrastructure and conditions of habitation (sewer, gas, storm drains, flood streets). This lack of access to services increases household living costs (purchase of water cans, gas from a carafe) and worsens sanitary conditions (floods, streams, lack of sewers). The situation of spatial segregation is combined with a certain favelization. And, poverty is presented as structural against which *the battle*

was lost²², where social programs “served as a cushion to moderate the increase in the number of poor”²³

In this context, fear and anxiety, along with boredom and worry, constitute the threads that bind behaviors such as Weber’s iron cage towards this population, where the quarantine in response to Covid-19 crystallizes the non-thematization of entering/leaving.

Fear conditions life, from here it is necessary to consider that it is the emotion most pronounced by the recipients of a social program, from the emergence of Covid-19 and the various modes of isolation in the global order. Fear as a coagulation mechanism of action (Scribano, 2007), in terms of Elias (1993) is established as a coercion that operates on individuals in the configuration of violence.

In this way, the 21st century, paraphrasing Elias in this “new civilization,” opens the doors for a new emotional constraint, which encompasses the inner world; that is, not only the social construction of emotions but also the social construction of the world’s perceptual apparatus, and with it the construction of sensation (Scribano, 2020).

Chapter 497

SENSIBILITIES OF EATING INSIDE: EMOTIONS AND FOOD PRACTICES IN A TIME OF A PANDEMIC

Aldana Boragnio*

Center for Research on Consumption, Sensitivities and Creativity (CICSEC),
University of Palermo, Argentina

ABSTRACT

In the pandemic situation, where social distancing and confinement were presented as the main tools for its prevention, eating became confined to the inside of the home. For those who have a home to stay in, eating has been reinstated as a practice in the private sphere and as a need to be met while remaining indoors. Eating is a daily practice that produces and reproduces the body, and it is shaped from habits, norms and customs that are expressed in social sensibilities. At the same time, it is directly linked to the configuration of emotions as the body/food/hunger/emotions relationship unfolds in an unbreakable continuum. While the diet is configured as a set of practices that are practices of the politics of sensibilities, food and commensality practices imply and express sociabilities and experiences. In this case, by knowing about diet, food practices and commensality, we will know how people put into practice specific knowledge about food to organize and regulate the planning, preparation and consumption of their daily meals in the context of isolation and of a new organization of time. Thus, knowing about diet and its practices will allow us to know the sensibilities and experiences in the context of a pandemic, where food practices take on a greater importance, since it highlights not only the possibilities of access, variation, diversification and consumption, but specific sensibilities around cooking, eating and the home. The objective of this chapter is to expose the sensibilities of eating in a time of pandemic in Argentina and Spain, based on a comparative study between the two countries. To do this, we conducted an online survey, self-administered during the first five weeks of isolation and confinement, and in-depth interviews with young people from the tenth week, seeking to discover the eating practices of isolation in articulation with the time/space relationship, which are configured from a politics of sensibilities as cognitive-affective practices of feeling in the pandemic world.

INTRODUCTION

The COVID-19 pandemic came as a surprise to many and was suddenly imposed, shifting from the news to mandatory confinement and isolation measures that not only immediately and strongly impacted the productive structure, but also immediately modified daily life in a way not previously known to many.

In Spain, the period of physical confinement and total social isolation due to COVID-19 –called the State of Alarm and Confinement (EAC, for its acronym in Spanish)– was established by Royal Decree 463/2020 on March 14, 2020. A few days later, on March 20, 2020, in Argentina, the Social, Preventive and Mandatory Isolation (ASPO, for its acronym in Spanish) came into effect. This new reality forced the subjects to not only modify their daily life, but also involved returning the home to the centre of all activities. Work, education, entertainment, training, and consumption were modified to be held indoors and in several cases, transformed to be able to be realized.

From the confinement and isolation policies due to the COVID-19 pandemic, food took on a new centrality in this context. First, it exposed the possibility of the lack of food amongst people who were born in the era of overabundance, while the fragility of the food system was exposed, reconfiguring this as an essential activity. During this period, eating was again configured as a practice inside the home, where, in many cases, it brought the subjects together again socially in the shared act. Thus, the reinstatement of eating as a practice in the private sphere and as a need to be answered on a daily basis within the home led to a readjustment of food practices and commensality.

The objective of this chapter is to expose the sensibilities of eating in a time of pandemic in Argentina and Spain, seeking to uncover the food practices and commensality practices in conjunction with the temporal/spatial relationship of confinement, which is configured from a policy of sensibilities as cognitive-affective practices of sentiment in the world of the pandemic.

The data presented comes from an online survey, self-administered, in which the food practices related to the purchase, cooking and consumption of food in households were investigated. The survey was carried out during the first five weeks after the implementation of the ASPO in Argentina and the EAC in Spain, obtaining 472 responses for the case of Argentina and 290 for Spain.

Secondly, from the tenth week of ASPO and EAC, in-depth interviews were conducted with young people from Spain and Argentina between 20 and 29 years old, since this age group was the one that offered the most responses to the survey. The main objective of the interviews was to collect information on the eating practices in isolation in conjunction with the temporal and spatial relationship of the period of exit from the prohibitions. Informed consent was requested to carry out the interviews and the anonymity of the participants was preserved. These were recorded and fully transcribed to be subjected to data analysis, classifying their content defined according to emerging themes.

The argumentative strategy will be as follows: a) a brief overview is offered of the relationship between body/emotions/eating from the standpoint of a sociology of bodies/emotions; b) the specificities of the concepts of food practices and commensality are explicated; c) the data from the surveys and interviews are presented, detailing the emotions

around eating and the changes produced by confinement; and d) some final lines are presented by way of conclusion and identifying future openings for inquiry.

EATING BODIES/EMOTIONS

When we talk about bodies and food we talk about bodies that eat. We refer to biological bodies that need to ingest food and nutrients for their reproduction, but also to the emotions that are configured from the availability and appropriation of daily energies. This occurs without ceasing to relate the social relationships necessary for this to happen. Thus, eating is not only central to the reproduction and social availability of bodies, but the organic/cognitive/affective is intertwined in the production and reproduction of bodies/emotions.¹

From the sociology of bodies/emotions, we understand that

“The bodies are such, given their connection with the environment/environment (material conditions of existence) through (and by) the complex processes that are generated in the interaction between (with and from) the brain/central nervous system/nutrients/energies. b) The brain “houses” (in a complex and indeterminate way) the processes of the social construction of bodies and emotions mediated by a set of interactive modularities between the chemical and electrical “causes” of the life systems that articulate the capacities that have nutrients/energies to enable/block, produce/reproduce and/or balance/unbalance the existence of those bodies/emotions. c) The unequal distribution and appropriation of nutrients/energies model the potentialities that the neurophysiological system has to “maintain” the possible states of life of the subjects as social agents. d) The processes of social structuring by “modelling” the possible connections between impressions/perceptions/ sensations/emotions and the brain/energies/environment are variables that co-embody the possible forms of bodies/emotions” (Scribano 2012: 97).

From this conceptualization, it is possible to observe the limits of a society that becomes a body, while bodies will be produced and reproduced within the limits of the material conditions of existence that society distributes unequally among subjects. In this sense, the relationship between bodies/environment/nutrients is essential for the conformation of bodies, at the same time that it will enhance/block the perceptual, emotional and cognitive capacities of those bodies as they grow.

Emotions will allow the subject to feel (himself), which gives him the capacity for action, understanding it as “action tendencies instead of specific actions” (Von Scheve & Slaby 2019: 10). But, emotions are not the result of a single cause/motivation but rather “are the result of the co-bordering² of a constellation of previous interactions between multiple factors” (Scribano 2018: 7) and, in their indeterminacy and complexity, they emerge from the processes of adjudication and correspondence between perception/sensation/emotion.

¹ The bar (/) implies the possibility of writing and inscribing the connections/disconnections that involve bodies and emotions and allows us to grasp/understand that seeing, tasting, smelling, hearing, feeling, perceiving, thinking, wanting, acting are complex, indeterminate moments and nodes through which the multiple subject/society relationships are woven (Scribano, 2012).

² “Cobordism is basically an equivalence relation between compact varieties. Two varieties are said to be cobordant if their alien union is the border of a third compact variety. As we will see, the border of a variety of dimension $n + 1$ is a variety of dimension n , and the border of a variety with the border is a variety without border” (Pérez and Ávila, 2011: 3). The main problem with cobordism is “knowing when two varieties can be deformed into each other without encountering a singularity in the resulting space, at any moment in this deformation” (Thom, in Wiley & Sons Aubin 2004: 103).

At this point it is important to note that the sensations are distributed according to the specific forms of bodily capital that are the conditions of existence housed in the body, understanding it from three registers: a) an individual body, which refers to the body as a biological organism, as an organism that has organs, functions and processes that are genetically constituted; b) a subjective body, which is found in the field of the “I” that constructs a narrative of its existence as a biography - in this plane, interactions and relationships with others take place; and c) the social body, which is the incorporation of learning, practices and habits that shape the body and that constitutes subjectivity from socialization (Scribano 2007).

This way of understanding the body with analytical distinctions that occur in an inter-crossed and superimposed way makes it possible to think of the connections between sensations and the body as a given state of affairs. In this way, the subject and her material conditions of existence are interconnected in dialectical tension with the result of feeling-in-a-body. For its part, talking about bodies implies talking about a politics of bodies, understood as “the strategies that a society accepts to respond to the social availability of individuals” (Scribano 2015: 35). In this case, the politics of bodies will organize socially accepted practices and strategies to respond to the daily need to eat in their relationship between bodies/environment/ nutrients.

On the other hand, all politics of the bodies implies a politics of sensibilities, which regulates how the actors experience the states of feeling and feeling the world. In this sense, the politics of sensibilities is linked to a

set of cognitive-affective social practices aimed at the production, management and reproduction of horizons of action, disposition and cognition. These horizons refer: 1) to the organization of daily life (day-to-day, wakefulness/sleep, food/withdrawal, etc.); 2) to information used to order preferences and values (adequate/inappropriate, acceptable/ unacceptable, bearable/unbearable) and 3) to the parameters for time/ space management (displacement/location, walls/bridges; infrastructure for the valorization of enjoyment) (Scribano 2018: 10).

This interconnection allows us to understand that the body/food/ emotions relationship is a central node in the structuring of sensibilities since eating elaborates, inscribes and reproduces the possibilities of living and narrating the world based on the potentialities and obturation that are nested in the distribution of nutrients and energies, constituting the possibilities of feeling-in-the-world from a-body.

EATING PRACTICES: FOOD PRACTICES, COMMENSALITY AND SENSIBILITIES

Now, if we talk about eating, we refer to a practice that subjects carry out throughout their lives and that, under ideal conditions, they should repeat a couple of times a day. At the same time, it must be taken into account that this practice can be carried out from a complex system of relationships that ranges from the production of food to the intake itself.

Eating practices encompass elements of a cultural, economic, social and individual nature, which intersect with the actions necessary to reach the act of eating. On the one hand, we find food practices, which as “the actions of obtaining, accumulating, preparing,

conserving food, together with the knowledge in this regard, held by a specific group in a specific historical context” (Boragnio and Sordini 2019: 74). And, on the other, commensality, which is organized based on habits, norms and customs.

Commensality is the way of eating typical of human beings. From omnivorism, and with the difficulties involved in obtaining the necessary food in solitude, sharing food became essential for the reproduction of the species, generating specific norms that constituted the moment of eating at the same time as a community of diners (Fernández-Armesto 2009; García 2013). Therefore, ‘eating’ is organized by cultural guidelines before the specific moment in which the food will be eaten. These guidelines will vary in each culture and will be modified according to gender, age, the social position of who eats along with the specific context of space/time where the act of eating will take place.

If commensality is the form acquired by sharing food among human beings, and if these forms are constituted by the set of social relations, the rules of commensality will focus on legitimate ways to carry out sharing. Thus, commensality has four main axes: rules/norms, time, space, types of interaction, the latter being the various ways of carrying out the rules/norms—every day, extra-daily, festive, in physical presence, alone—.

In western societies, from the twentieth century, the process of change called “food modernity” or “late modernity” began, in which commensality enters into crisis and the shared rules fall, producing a destructuring of eating behaviors (Fischler 1995, 2010; Contreras Hernández 2005). The entry of women into the labour market, the extension of school hours and working distances, the development of the food industry on a massive scale and the production of ultra-processed products, as well as the creation of a market segmented by income, they modified daily life, which led to changes in food practices.

The first modifications that were made focus on “de-structuring, de-socialization, de-implantation of hours and de-ritualization” (Poulain 2002). These “de-” tendencies are observed in three concrete practices of daily life: a) the simplification of the structure of food, making the dishes increasingly simple; b) the increase in consumption outside the home, making public a daily practice linked to the private; and, c) the increase in the number of ingestions, which separate the act of eating from a specific time, which amplifies both the hourly and spatial possibilities.

Within the framework of these changes, daily food tends to be linked to an extra load to the working day, which is quickly solved in the domestic environment, with ultra-processed industrial products. In this sense, food is no longer organized by family life, but rather, the strategies to provide a solution to the daily diet focus on individualism and the destructuring of intakes. In this way, “snacking”³ appears as the form that the subjects give to the current diet (Mintz 1996; Poulain 2002).

Although current commensality is not strictly unstructured and guided by “snacking”, the modernization of daily life, the value of time and the objectification of the body, have been continuously and deeply transforming the ways of eating, thinking and sharing the food. Thus, among the main changes in the rules of commensality is the shift of the choice of food to the individual scope, the loss of regulated times of eating, the increase in the number of times and the amount of intake, the monotony of food, the loss of culinary know-how and the ritualization of food as a consumer experience (Boragnio 2020; Aguirre et al. 2015).

³ Small portions of food or meals that are eaten at varied times, between main meals, but are not considered as a proper meal. Nutritionally the concept of snack is about what is called “junk food”.

The richness of commensality as a concept does not reside only in the specificity of the act of sharing food and the rules that are involved in that act, but also in the plurality of meanings and modes that it possesses. So, as we can see, the experience of eating will be traversed by the politics of bodies and commensality. In this way, from before birth and reinforcing themselves in the daily act of eating, people are articulated with the social structure based on habits, norms and customs that are expressed in social sensibilities.

As we can see, eating practices have a dynamic character, so they are able to readjust depending on the context, but always within the sociocultural system that gives meaning to commensality. Next, we present the main characteristics of eating in Argentine homes, then the details and pictures of eating in Spanish homes will be outlined, and then we will focus on sharing the emotions and sensibilities linked to both countries.

EMOTIONS OF EATING AT HOME

Eating in Argentine Homes

When asking respondents what place food occupies in their lives, 76.4% of Argentines gave scores of 7 upwards, the mode is 8.

Figure 1. Place of food in life, Argentina.

Figure 2. Emotions when eating in Argentina.

Figure 3. Word cloud of the responses of young people aged 19 to 29 in Argentina.

For young people from 19 to 29 years old, the mode about the level of importance of food is also 8, but the responses that indicated a value of 7 or more are 86%.

When the respondents were asked to indicate with three words what they felt when eating, the predominant responses, in order of frequency, were: satisfaction, good, happiness, tranquility, glad, very good, grateful, guilty, pleasure and normal. If we add the answers obtained for “good” and “very good” we can produce a category of “well-being” that would have the first place.

For their part, respondents aged 19 to 29 indicated that their feelings were mainly focused on satisfaction, happiness, good and glad. But we also find repeated responses such as enjoyment, calm, full, anxiety, energetic and healthy.

Eating in Spanish Homes

When asking Spaniards what place food occupies in their lives, 84.55% gave scores higher than 8, this being the mode.

Figure 4. Place of food in life, Spain.

On the other hand, in a population of 19 to 29 years of age in both countries, responses are the same. In Argentina, the three most repeated emotions are satisfaction, good and happy, while in Spain they are also good, happy and satisfaction. As for differences, we find that young people from Argentina also indicate feeling glad, enjoyment, anxiety, full, healthy and grateful; while young Spanish people feel comfortable, grateful, satiety, full, guilty and healthy.

EATING IN TIMES OF CONFINEMENT

When analyzing the data from the surveys and interviews together, new axes appear to take into account when thinking about the eating practices at home in times of pandemic. Among the main changes shown by the data are not only changes in what is eaten, but also in food and commensality practices.

The first modification that appears as a positive change and, at the same time, as a negative change for the research participants, is the routine of schedules. The changes in the schedules are expressed mainly in the fact of skipping a meal as in the incorporation of breakfast daily.

"I consume less purchased food, more snacks and breakfasts, also simpler meals" (26-year-old female, Argentina)

"I have disorganized schedules, I eat junk food in excess as a snack" (29-year-old female, Spain)

Thus, the change in schedules allowed the subjects to organize the day, but as we can see, it also disorganized it.

On the other hand, schedule changes are directly related to changes in the menu. First appears the need to plan different menus since having to eat every day at home, taking charge of the entire purchase/planning/cooking process, and the need to innovate are imposed so as not to fall into monotony. As the interviewees tell us:

"I cook more, I got out of the dynamic of always eating the same thing." (28-year-old female, Argentina)

"I believe that at some point during this quarantine we have all made, even if it is an attempt to cook, that, although you are not always cooking throughout these days, you have tried. (...) The week has 7 days, you have to be cooking the same thing so to speak, but in 7 different versions." (25-year-old female, Spain)

These variations in the dishes were not only introduced by the need to eat other things, but could be achieved by the time available, which offered the possibility of cooking new things, of being able to dedicate time to the kitchen and more complex preparations.

"I like to vary from what I always eat because I have more time to look at recipes and cook them." (23-year-old female, Argentina)

"Take advantage of the time to make healthier and more elaborate meals." (24-year-old female, Spain)

Based on this, surveys show that the new preparations made in Argentina and Spain focus on the mains, sweets, followed by dishes that were frequently consumed, but made in a homemade way. With this, the interviewees indicate that they began to cook as a new quarantine practice, and those who already cooked before took advantage of the time to make more elaborate and complex dishes.

"Instead of buying, it was replaced by making it at home." (24-year-old female, Argentina)

In this case, it is striking that in surveys in Spain pride appears as an emotion linked to eating in a pandemic, since respondents were able to realize that they can cook and do it well.

"I am proud of the menus that I am making, but stressed by the amount of flour." (21-year-old female, Spain)

Along with the kitchen, there is the stress of flour consumption and the multiple strategies to limit its consumption and implement and sustain the consumption of healthy foods. About this, in the surveys, it can be observed that the search for a healthy diet is one of the main axes, either to stay healthy at this stage, to avoid getting sick, and not to gain weight. For this, respondents and interviewees tell us they choose light, healthy foods.

"I vary foods to maintain a balanced diet weekly." (20-year-old female, Argentina)

"I try to maintain a balanced diet (salad, baked vegetables)." (24-year-old female, Spain)

At the same time, although most of the answers about the diet in the days of isolation focused on being happy and satisfied with it, it was also clearly emphasized that there was something wrong and it was marked as something to be modified.

"Although I did eat and we eat super healthy, I know that we ate unnecessary sweet things." (23-year-old female, Argentine)

"Are you satisfied with your diet these days?"

No, I would like to eat healthier." (23-year-old female, Spain)

In this sense, several respondents said they were on a diet and/or going to a nutritionist. Among those who said they consulted a nutritionist, almost all went before the isolation period and tried to maintain the diet.

"It depends on what you are eating. When I eat every day I feel good, and I like to eat balanced and think about combining different foods. When I eat something out of the ordinary (something more "fattening") I enjoy it a lot at the moment and eat everything I think I want but knowing that later I will be blamed or I will feel very full." (woman, 24 years old, Argentina)

"It depends on what you eat. If I eat healthily I feel good. If I go off my diet I feel guilty, bad." (28-year-old female, Spain)

We understand the need to go to the doctor to learn how to eat as the loss of knowledge concerning eating practices occurs from multiple factors within food modernity. On the one hand, due to the separation between the social norms of eating, the separation of food production, the reorganization of the times where it is no longer clear what is eaten at what time and the deregulation that occurs from individualism to eat alone. Then, the cacophony (Fischler 1995) generates an excess of discourses that have as consequences the uncertainty about which one to follow, since all are expressed under the label of "the truth". This, added to the medicalization of food that led to the de-hierarchization of women in eating issues (Boragnio 2020b), which place them as the unauthorized voices and, therefore, in the space of non-knowledge. But, at the same time, we observe that this time of change in the period of the ASPO and the EAC, provided the possibility for the youngest to approach the kitchen as a way of doing, of transforming daily life, not only not to be "eating the same" but to try to "feel good."

BY WAY OF CONCLUSION: SENSIBILITIES OF EATING INSIDE

The confinement and isolation decreed by the spread of COVID-19 led to a rethinking of food practices and commensality, configuring eating practices as a central node of daily life during the pandemic. In this case, eating as a daily act that had been turned into the public sphere –from the implementation of multiple modifications in domestic, school and work-life– was redirected to the interior of the home, once again becoming a domestic and family activity. From this change, new rules of commensality were generated. On the one hand, this centered around the types of interaction that became entirely domestic and every day. And, on the other, they were configured in relation to the time and space that allowed subjects, in some cases, to re-order the daily diet.

The period of confinement and isolation brought young people closer to the practice of cooking, generating emotions of satisfaction and pride. As the body/food/emotion relationship develops, we can observe that the action of cooking seeks well-being, satisfaction and containment. But at the same time, the introduction of the multiple discourses, of a politics of sensibilities around “nutrition”, reproduces the idea of not knowing how to eat. At the same time, the practice of eating is configured as an individual learning activity. In this way, the experience of eating is articulated in young people between guilt, anxiety and enjoyment.

Nutritional sensibilities organize and classify preferences and values where health is put first when choosing what to eat. Eating is no longer organized based on calendar dates or family knowledge, but eating practices are structured by a mediated medicalization based on nutritionism configured as a sensibility to eating. Thus, the diet is configured as a set of practices that are practices of the politics of sensibilities, while the food practices and commensality imply and express different sociabilities and experiences.

From the emotions linked to eating, we can observe the connection of this as a cognitive-affective social practice, which not only tends to the production and reproduction of the body in its materiality, but also to the production and reproduction of the individual and social energies that will constitute the possible horizons of action, disposition and cognition. Eating organizes daily life. In isolation, the day is spent thinking about what to eat, when to eat, what to do to eat. But, at the same time, eating orders the day, orders the hours, what is eaten during the day, at night, based on the rules and norms of commensality.

Finally, it is important to point out that, as we can see, eating is organized based on parameters for other time/space management. In this sense, in the period of isolation and confinement, when public time/space was unable to inhabit for many –while many others inhabited it without the possibility of autonomy or decision– domestic time/space was reconfigured and multiplied. At this time, cooking was once again the main axis of daily life at home. And although industrialized foods, service foods and ultra-processed foods continue to be the edibles that reproduce eating at home, the new time allowed other possible ways of eating to be explored. Whether they are reproducing what was consumed outside at other times or producing something new, the traditional, the common shared at home, the commensality that builds edibles into food.

In this way, from the eating conditions of life and its reproduction are molded –as nutrients configure the bodies and emotions– at the same time that the ways of experiencing eating and experiencing the body are defined by possible foods and their taste, diners are

configured and social relationships are hatched. In this sense, the consequences of eating become evident in the structuring of sensibilities, based on regimes that constitute particular ways of regulating, ordering and incorporating social practices in specific socio-historical contexts.

Eating is a key determinant of people's health, but also of their daily emotional experience. This pandemic reality not only affects food practices and commensality, but also affects and configures the emotions. A long way ahead is the analysis of the eating practices of young people, to learn more about the diet that they put into practice, their knowledge and specific strategies for planning, preparing and consuming their daily meals, to know the relationships between body/food/emotions in the post-pandemic 21st century; with the final interest of being able to approach the transformations of the set of cognitive-affective social practices aimed at the production, management and reproduction of horizons of action, disposition and cognition. In other words, being able to know the policies of the sensibilities that are currently being formed.

The lines of inquiry presented in these pages allow us to continue deepening the interconnection in the relationship between body/food/ emotions as the central node in the structuring of sensibilities, since eating elaborates, inscribes and reproduces the possibilities of living and narrating the world from the potentialities and obturation that are nested in the distribution of nutrients and energies, by constituting the possibilities of feeling-in-the-world from a-body. And that, in confinement, allowed people to reconnect with others, with co-living, reproducing the social bond that modifies nature to make it a body and that builds commensality as the only human way of eating.

DIE ALONE IN ARGENTINA: A VIEW FROM SENSIBILITIES IN TIMES OF THE PANDEMIC

Adrián Scribano^{1,*} and Jorge Duperré^{2,†}

¹CONICET, Argentina

²Universidad de Palermo, Buenos Aires, Argentina

ABSTRACT

The objective of this work is to reflect on the sensibilities related to dying and death, in the context of the current coronavirus pandemic. The presentational strategy that we have envisaged in this regard begins by defining and establishing the theoretical perspective in which our proposal is framed: the sociology of bodies/emotions. Then we go back to another global crisis that occurred a century ago, known as the Spanish Flu. The reason for this is to recover some antecedents that allow us to enrich our approach to this phenomenon that is still ongoing; not in comparable terms (since both episodes are not), but rather illustrative. Finally, we will deal with the three traits that, in our opinion, characterize the collective bond with the dying and corpses at the present moment: mediated death, regulated death, and cherished death.

INTRODUCTION

The pandemic (and its management) implies a politics of sensibilities that has at least three relevant characteristics for what we want to illustrate here: a) a geometry of bodies where the proximity and distance between human beings is re-structured around the medical gaze on the healthy/sick, b) a grammar of action where the definition of who the other is operates from the denial of physical contact and c) the redefinition of the ghosts and fantasies associated with the threat of death (Scribano 2020, Scribano and De Sena 2020). Having pointed out the above, we must recognize that we are witnessing a time when all horizons of

comprehensibility and expectations become strange, opaque. Policies of distancing and preventive control alter the dynamics of social interaction, public space appears alien and threatening, and public and private institutions try, in their own way, to adapt to the challenges presented by this uncertain situation¹. Meanwhile, in the academic sphere, numerous experts are quick to characterize the current crisis as a *total social fact*, thus dusting off the analytical category that Marcel Mauss coined almost a century ago - such is the magnitude and severity of the pandemic disease, caused by the COVID-19 coronavirus. As it could not be otherwise, the catastrophe was able to acquire public notoriety as the number of deaths increased throughout the world. Just to name a few cases: on the occasion of approaching 100,000 US fatalities from the pandemic, the prestigious American newspaper *The New York Times* published, on its cover on Sunday, May 24, a list with the names of a thousand of them, accompanied by the following reflection: “They weren’t just names on a list, they were us”². Exactly two weeks earlier, the similarly prestigious Brazilian morning newspaper *O’Globo* had done something very similar, as a way of paying tribute to the 10,000 lives that COVID-19 had claimed so far in the country³. And the newspaper *ABC de España* denounced, on September 13, that the real death figures were double the official figures (53,000 compared to the 26,000 reported). The design chosen for this cover highlights the difference between the two figures, which are framed by drawings of hundreds of identical tombstones⁴. The funeral notices, for their part, witnessed how the death rate soared in the most affected cities. Such is the case of the newspaper *L’Eco di Bérgamo* (an Italian city in the Lombardy region), which, at the beginning of February, allocated only a page and a half to the obituaries, and a month later that section had reached 10 pages⁵, or *The Boston Globe*, which went from a Sunday average of seven pages to 21 on April 26⁶.

No one can foresee what political and social order will ensue. The truth is that life will not pass in the same way; neither will death and dying. Aware of how problematic it is to analyze a phenomenon still in the making –whose human and material losses are impossible to foresee in the long term– we have resorted to a precedent that, although not comparable to the present situation, gives us some keys to understand the social implications of the management of death and the dead in the context of a pandemic. We refer to that episode baptized by history as the Spanish Flu, which would claim around 50 million lives across the planet in a short period of time (1918-1920).

¹ Even the language itself has been affected by this unique situation. And it is that, for some time now, countless neologisms related to the disease have populated everyday speech. To cite just a few cases: the “zoompleaño” is a form of celebration mediated by technological devices, which has become popular during confinement; “Infodemic” is the term with which the World Health Organization (WHO) designates the massification of false or imprecise news that circulates through the media and social networks; the verb “quarantine” has to do with the voluntary action of remaining isolated; “Coronials” refers to the generation that will be born from now on. For more information on this, visit the following website: https://www.clarin.com/cultura/covidiotazoompleanos-coronials-nuevas-palabras-trae-coronavirus_0_f3apTIQIP.html

But before entering into the problematic that summons us, we consider it necessary to make explicit the theoretical perspective from which we make our approach, namely: a sociology focused on *sensibilities*. By virtue of this, we will briefly review the theoretical-methodological and epistemological postulates on which it is based, and the centrality that the corporal/affective dimension acquires in this framework, as a fundamental indicator for the study of social structuring processes.

Once these guidelines are provided, we begin to analyze the three contingent traits that, in our opinion, make the transformations of behavior in the face of current dismissal and separation disruptive. Let us review each of them: a) a relative accentuation of that confining tendency (*ethos* of “*homo clausus* Hospitable”) and desacralizing (*ethos* of the “*homo luctuosus* Secular”), noted by Norbert Elias (2009), regarding the way in which, on the one hand, the dying person is compelled to spend their last hours, and, on the other, is cremated when dead. This is a tendency that finds, in the interaction mediated by technological devices, certain mitigating factors; b) the abrupt alteration of the standardized practices of treatment and disposition of the corpse, as a result of the appearance of new mortuary dispositions, which directly affect the health system and the funeral market; and c) the debate on “bad death” and “good death”, which puts the accent on the dignity of the suffering or deceased and, simultaneously, certain prevention campaigns whose “insolent” narratives update rhetoric typical of the grotesque, which come to question certain values traditionally associated with farewell rites.

We consider that these three traits - “mediated death”, “regulated death” and “reverent/irreverent death” - suggest possible plots about bodily distancing (the dying person, and then his remains, as an agent of contagion) and emotional expressiveness (the socialization of pain forbidden), which are symptomatic of the present moment; these are plots that - and this is where our working hypothesis lies - would show how sensibilities around human death are reconfigured in this context of humanitarian crisis.

OUR THEORETICAL PERSPECTIVE

In a broad sense it is necessary here to make some clarifications aimed at explaining some starting points about a sociology of sensibilities (Scribano 2017, Scribano 2018). We consider that humans know, build and rebuild the world in and through our bodies and emotions. The most elemental form of alluded contact is the social construction of the connections between perceptions, sensations, and emotions: this builds a tripod that allows us to understand where sensibilities are founded. Thus, a set of impressions impact in the ways that subjects “exchange” with the socio-environmental context. Such impressions of objects, phenomenon, processes and other agents structure the perceptions that subjects accumulate and reproduce. Perception, from this perspective, constitutes a naturalized way of organizing the set of impressions that are given in an agent.

This weaving of impressions configures the sensations that “produce” what can be called the internal and external world: social, subjective and “natural” worlds. Such configurations are formed in a dialectic tension between impressions, perceptions and their results, that give sensations the “meaning” of a surplus or excess. Therefore, it puts them closer and beyond such dialectic. Sensations, as a result and as antecedent of perceptions, locate emotions as an

effect of the processes of adjudication and correspondence between perceptions and sensations. Emotions, understood as the consequences of sensations, can be seen as a puzzle that becomes action and effect of feeling something or feeling oneself. Emotions are rooted in the “state of feeling” the world that allows the sustaining of perceptions. These are associated with socially constructed forms of sensations.

At the same time, organic and social senses also enable what seems unique and unrepeatable, as are individual sensations, and elaborate the “un-perceived work” of incorporating social elements turned into emotions. Sensations, as a result and antecedent of perceptions, give way to emotions which can be seen as the manifestation of the action and effect of feelings. They are rooted in the states of feeling the world that build perceptions associated with socially constructed forms of sensations.

Consequently, the politics of bodies (i.e., the strategies that a society accepts in order to offer a response to the social availability of individuals) is a chapter –and not the least important chapter– in the instruction manual of power. These strategies are tied and ‘strengthened’ by the politics of emotions that tend to regulate the construction of social sensibility.

Politics of emotions require regulating and making bearable the conditions under which social order is produced and reproduced. In this context, we understand that social bearability mechanisms are structured around a set of practices that have become embodied and that are oriented towards a systematic avoidance of social conflict.

The forms of sociability and experience are strained and twisted as if contained in a Möbius strip along with the sensibilities that arise from regulatory devices and the aforementioned mechanisms. The need to distinguish and link the possible relations between sociability, experience and social sensibilities becomes crucial at this point. Sociability is a way of expressing the means by which agents live and coexist interactively. Experience is a way of expressing the meaning gained while being in physical proximity with others, as a result of experiencing the dialogue between the individual body, the social body, and the subjective body, on the one hand; and the natural appropriation of bodily and social energies on the other. For the body to be able to reproduce experience and sociability, it is necessary that bodily energy is an object of production and consumption. Such energy can be understood as the necessary force to preserve the state of ‘natural’ affairs in a systemic functioning. At the same time, the social energy shown through the social body is based on bodily energy, and refers to the allocation processes of such energy as the basis of the conditions of movement and action. Thus, sensations are distributed according to the specific forms of bodily capital; and the body’s impact on sociability and experience shows a distinction between the body of appearance, body of flesh, and body of movement.

Social sensibilities are continually updating the emotional schemes that arise from the accepted and acceptable norms of sensations. They are just a little long or short of the interrelationships between sociability and experience. Sensibilities are shaped and reshaped by contingent and structural overlaps of diverse forms of connection/disconnection among various ways of producing and reproducing the policies of the body and the emotions.

The politics of sensibilities are understood as the set of cognitive-affective social practices tending to the production, management and reproduction of horizons of action, disposition and cognition. These horizons refer to: 1) the organization of daily life (day-to-day, vigil/sleep, food/abstinence, etc.); 2) information to sort preferences and values

(adequate/inadequate, acceptable/unacceptable, bearable/unbearable); and 3) parameters for time/space management (displacement/location, walls/bridges; enjoyment).

In this context the pandemic is itself an alteration to the policies of sensibilities and in this context of how we live death; on this we offer some considerations in the following sections.

THE SPANISH FLU AS AN ANTECEDENT

All pandemics have a high social component in their genesis, reproduction and management, as Henao-Kaffur and Hernández-Álvarez (2017) say in the case of the “Spanish flu”, a feature that impacts is the suddenness of deaths and the volume of them.

A feature that “death management” shares with “epidemic management” for both the Spanish Flu and COVID-19 is the isolation they produce, as summarized by Mejías Estévez, Domínguez Álvarez and Blanco Reina (2018), regarding that catastrophe at the beginning of the 20th century:

The tragedy of this pandemic went beyond direct deaths. Fear seized the population, causing dramatic situations such as social isolation and the stigmatization of the disease. People were absent from their jobs (they did not dare to leave home), producing a direct and disastrous effect on the economy. In some places the authorities declared a quarantine, prohibited the right of assembly to avoid crowds, schools, theaters, centers of worship were closed ... to the point that numerous deaths of children were due to hunger (they were isolated to the point prohibiting bringing them food). (p. 665)

In this section we want to refer to how the disposition of the dead was treated in the aforementioned pandemic, as a precedent of what has happened in the case of COVID-19. It is obvious that we only undertake this in an attempt to make evident some axes of possible inquiry, but also to suggest that it is feasible to analyze similar phenomena in other times.

The British military doctor Roy Grist, who was attending Devens Camp, northwest of Boston (USA), offers the following description:

... we have lost many doctors and nurses ... special trains are needed to transport the dead. For several days there were not enough coffins and it was necessary to pile up the dead. A large barrack has been vacated to adapt it as a morgue ... where the corpses rest in double file ... (Roy Grist, in Murrillo Godines 2011: 463)

A central problem is the space to deposit, bury and incinerate the corpses, their transfer, and their isolation. In special areas, cities and regions in a pandemic situation must manage lifeless bodies and thereby inaugurate differential and unequal body geometries. For the same spatio-temporal context, González Bombardiere (2007) states that:

When mortality rose to 500, 600 and 800 deaths per day, the corpses began to accumulate, there were not enough funeral homes or gravediggers, and fewer coffins. People refused to bury the dead from influenza for fear of contagion. (p. 42)

The dead and fear as a sign of the pandemic and its effects are associated with a grammar of the action of burial as a specific undertaking. All cultures have developed specific roles for those in charge of conditioning, transporting and burying their dead, practices that are

modified in a pandemic: since they are not enough, given the large number of deaths. Without coffins and without sufficient gravediggers, the structure of roles and positions is modified.

Regarding the Argentine case, Adrian Carbonetti (2010) has written:

The measures taken by the State tended to harden in November of the same year: congregations and assistance to cemeteries were suspended on the day of the dead (...) The provisions they were different in each district; thus, in the case of the province of La Rioja, these reached extremes such as the prohibition of attending wakes, except for the bereaved (p. 172)

Another modification that occurs in the Spanish Flu is that of ritual practices, which in turn, impact on the politics of the sensibilities associated with grief. The prohibition on attending cemeteries and wakes (except for the bereaved) is a clear sign of the objective difficulty of producing the practices of feeling associated with mourning and the public expression of pain. These factors end up having an impact on the social, in terms of emotional disorientation, given the key place for social affective reproduction that these practices have for society as a whole.

When Márquez Morfín and Molina del Villar (2010) analyze what happened in Mexico City, they maintain that:

In the General Hospital, 43 had already died out of an admission of 200 patients. Due to the large number of deaths, a ditch was being opened near the Pantheon from Santa Paula, where bodies had been buried during a cholera epidemic in the mid-19th century. (p. 142)

Another basic component of burial, at least in the emotional geocultures mentioned here, is the double loss that common graves produce: the loss of a loved one and the loss of their identity among many. Again, the mechanism of grief is altered, to which is added that of memory and the personal memory of those who have been lost. In her doctoral thesis María Isabel Porras Gallo (1994) entitled “A City in Crisis: the 1918-19 flu epidemic in Madrid”, makes the following components of the Spanish fever visible in the Spanish capital:

But the difficulties for citizens did not end when they died after being struck by the flu. The problems then arose at other levels: there was a shortage of vehicles to transport the corpses to the cemeteries; coffins were sometimes missing; new cemeteries had to be set up; and it was necessary to suspend religious ceremonies and any sign proper to burials. (pp. 89-90)

And later she adds that:

It is important to highlight that, although part of the Madrid population had health care through the medicine, burial and pharmacy societies, a very large population of Madrid had to go to the Private or public charity to receive medical assistance. (p. 164)

The situation in Madrid corroborates what has been described for Argentina and Mexico, emphatically pointing out the connection between the pandemic, the health system, the state and social position. The pandemic is a matter of state that puts the magnifying glass on the constitutive inequality of a system that denies itself as enclosed. In the same way as yesterday or today, the question arises: in what type of social structure did the pandemic appear? It is

relevant for the structuring of resignation as a basic citizen emotion that will continue to this day in its “subsiadiano”⁷ form (Scribano, 2019).

Finally, it is very interesting to notice the news about the flu published in the *Rif Telegram* on June 11 of 1919, that Daniel Castrillejo Pérez (2019) reproduces in his article “The ‘Spanish’ flu pandemic of 1918-1920. Analysis of mortality in Melilla”:

THE FLU SPREADS

HEALTHY MEASURES BY THE AUTHORITIES

The flu epidemic has made its appearance again in Melilla and its territory with the same intensity as last winter.

Many cases are recorded daily, some with dire consequences.

In hospitals, nursing has increased in a disturbing way in the last week.

The Deputy Inspector of Health has brought what is happening to the knowledge of the Commander General, and in anticipation of greater evils, he has ordered the hygiene measures adopted last year to be put into effect again, relative to the permanence of the corpses in the houses, persons who must attend the funerals and careers that they must follow.

Disinfection of the closed premises, of great attendance, will be carried out, and the provisions regarding the collection of garbage from homes will be taken into account.

As can be seen, the authorities are not careless in the performance of their duty. Now it requires that the neighborhood not stop lending its assistance to the health work that circumstances advise.

We will very much celebrate that the causes that motivate these measures disappear as soon as possible. (As cited in Castrillejo Pérez, D., 2019: 135)

The persistence of death management policies in African Spain clearly indicates that the “overflow” of societal mechanisms to administer, prepare, transport and dispose of dead bodies is a feature of the Spanish Flu that helps us to understand what happened 100 years later with COVID-19.

DEATH AND DYING IN ABSENTIA

Let us now turn to the first of the traits that characterize today’s dying and death: the experience experienced in a mediated way. To chart the terms in which we think about this phenomenon, we can refer to an event that took place in Milan (Italy), in mid-March. At that time, this and other cities in the country were going through one of the most pressing periods of the health emergency: massive contagion, collapsed hospitals and cemeteries. It was then that a councilor from the Democratic Party, along with other members of that group, promoted a suggestive project consisting of the donation of *tablets* to terminally ill patients, in order to alleviate the anguish caused by spending their last days in absolute solitude⁸. Under the slogan “the right to say goodbye”, the group headed by Lorenzo Musotto made it possible for patients who had been admitted to an intensive care unit (IDU) to communicate

⁷ The expression in Spanish that refers to the union of subsidized and citizen as a new modulation of the relationship of people with the state is maintained here.

⁸ To read more about it, go to: <https://www.infobae.com/america/mundo/2020/03/18/el-derecho-a-decir-adios-la-donacion-que-conmueve-a-italia/>

for the last time with their families, through video calls. In his Facebook account, the councilor stated that: “The idea of not being able to say goodbye hurts me more than death itself [...] I know of the importance of masks, gloves and medical instruments, but the right to say goodbye, for the who leave and for those who stay, it should not be less “. It is noted here that the affective bond is of the same importance as health care. At this point, a characteristic feature of the COVID-19 pandemic can be observed: the transformations in the goodbyes, in the last goodbyes, point in the direction of an awareness of a reflective act on the meeting, on the co-presence (*sensu* Giddens). Consumer capitalism, societies normalized in acts of immediate enjoyment, the vertigo of a society thrown into the accumulation and depredation of the planet put aside, put in parentheses, did not give importance to the fact that all these activities were given by the encounter, for the accompaniment. The pandemic interrupts noise, speed and demands a new redefinition of the encounter with others, and very radically so about the last encounter; death challenges us to think of life as always. In this direction, it can be argued that, by investigating how societies deal with death, there are clues to the way in which these societies define encounters. Death in the context of COVID-19 becomes a demand due to the urgency of redefining what is everyday unthought in co-presence.

With regard strictly to mortuary rites, in our country there have been services for a few years that allow non-participation *in-praesentia* in the farewell of the deceased; an alternative that, in these circumstances, is worthwhile. Among them, we highlight the one provided by two companies: a) Almavis⁹ (a compound word that combines the terms “soul” and “notice”) from the Province of Córdoba. According to what it announces on its website, it deals with providing “technological solutions” to the local and national funeral sector, specifically in everything that has to do with “multimedia condolences.” Among the tools they sell are: the “Virtual Cemetery” (a place relatives can access to view the profile of the deceased, upload content in different formats, leave greetings, etc.), the “Smart Module” (a screen with a Wi-Fi connection that plays the messages sent by the bereaved while the wake is being held), a “mobile app” (through which funeral notices from the town specified by the user are received) and the “Plaque with code” (a device that is placed on the tombstones in order for visitors to share a message, condolences or words to relatives in the profile of the deceased; b) Grupo Pieve¹⁰, from the Province of Salta, offers the option of “Wake online”, that is: “follow the wake of your loved one if he is outside the province or the country through the cameras that are located in our Wake-Up rooms and we also have a PC so that you can communicate through a video conference with the person you want to accompany.”

Similar services are provided by other companies such as the Previnca Group of the Province of Santa Fe or Previsora del Paraná, which has branches in numerous cities in Corrientes, Chaco, Misiones and Formosa. One aspect that appears frequently in all its advertisements in this regard is the importance of the human bond (although not *in absentia*), to face the anguish generated by the death of a “loved one”.

Virtual obituaries (inheritors of the traditional funeral notices that even today have a specific section in the written press), are nothing new in the mortuary category, but today they acquire greater visibility with the sophistication of ICT and the expansion of social networks. In such a way, nowadays, the relatives have countless interactive tools for the

⁹ The mission of the firm is: “to revalue the services provided at the moment the mourning process begins”. Website: <http://almavis.com.ar/nosotros>

¹⁰ In the “Grief” “tab”, the client finds several “useful tips” to better cope with a “loss”. Website: <http://www.grupopieve.com/sepelios.html>

commemoration of their loved one (greetings, reminders, events, etc.). To cite just one example, some firms promote candles and virtual flower arrangements, which clients can light and/or give away (symbolically), as an additional way of honoring the deceased. In the specific case of social networks, Facebook, for example, allows people close to a deceased user to manage their account to receive condolences, reminders, thanks and other communications.

Circumstantially (or not), the “Social, Preventive and Compulsory Isolation” –decreed by the Argentine government in March, and still in force in much of the national territory–, has radically changed the way we conduct ourselves before the dying and deceased. By virtue of this, legal, business and hygienic discourses –which knew how to permeate moral and affective imperatives at death and after, or preventive/palliative logics– seem more ancient than ever. In this framework, technological devices would contribute, to some extent, to suture the disunity resulting from this new “body geometry” (Scribano, 2007), and thereby attenuate the emotions generated by not being with (or feeling) who “is just gone” or will soon be.

In this context, one of the most interesting and important “concerns” of preventive isolation is generated, referring to the impossibility of witnessing death and therefore the impossibility of living it, since we live death through the death of the others. Beyond the sadness, pain or indignation that the death of a loved one can cause, not being able to live it makes it impossible to go through grief in the way that our society has long designed and designated this process. In this case, two moments of the same process converge related to not being able to be next to each other, and not being able to live death through the other. On the one hand, it appears to us as an impossibility of accompaniment and, on the other, as an impossibility of saying farewell. Accompaniment and farewell constitute the central axes of our relationship with death; a measure of health policy turned into a thanato-political strategy that involves the anguish and anxieties associated with the experience of death.

THE DANGEROUSNESS OF THE CORPSE: HOW TO PROCEED

In line with the previous point, we have been able to survey a set of provisions that Argentine national, provincial and municipal authorities have recently promulgated on preventive matters. Among them, we distinguish, due to the nature of their prescriptions, two regulations published on last April 23rd: a) “COVID 19. Recommendations for the Management of Corpses”, of the Ministry of Health of the Nation (MSN); and b) the “Procedure for the Management of Corpses of COVID-19 Cases”¹¹, from the homonymous portfolio of the Government of the Autonomous City of Buenos Aires (MSGCABA). Let’s review some points that are of particular importance for our analysis:

As anticipated in their titles, documents do not have the status of a mandatory compliance standard; they are, rather, recommendations or suggestions regarding how to proceed in the face of an inanimate body suspected of infection. The reason for this is the lack of

¹¹ The Buenos Aires government clarifies that the prescriptions included in this document complement the “Protocol for the treatment of corpses, stillbirths, segments and anatomical parts in GCBA hospitals”, approved in 2014, and in force to date. This material is available at: <https://www.buenosaires.gob.ar/sites/gcaba/files/protocolo.pdf>.

information on, for example, the risk of contagion from the corpse and how long this risk may last. This is how the texts express it, in their introductory parts:

There is currently no specific guide for the management of corpses of people who have died from COVID-19, but the provisions of the published World Health Organization Guidelines may apply. in 2014 on Prevention and control of acute respiratory infections with epidemic and pandemic tendencies during health care ... (MSN: 1)

Notwithstanding that, to date, the existence of a risk of infection from corpses has not been solidly evidenced of people killed by COVID-19, in accordance with the precautionary principle and what is observed for other viruses that affect the respiratory tract, it is considered that the corpses could pose a risk of infection for people who come into direct contact with them (MSGCABA: 4)

As a result of these conjectures, the authorities suggest that health and funeral personnel reduce the tasks related to the treatment, transfer and disposal of the eventually infected corpse to the minimum (respecting, they add, the “human dignity” attributed to the deceased person, and the diversity of rites and creeds professed by the deceased¹²). In addition to autopsies, it is recommended to avoid “cleaning actions” and conservation (thanatopraxy) and cosmetic (thanatoesthetic) practices. Thus, a central axis of the relationship between the pandemic and death is revealed: the body as a witness to the potency of the virus, the threat of the virus, and the brand of the virus for the future. It can be clearly seen how the connection between aesthetics and politics takes a dramatic turn: presenting the body is already a risk and death is once again killed, since, if death separates the living from the dead, this is a form of death that separates the dead.

The custom of holding a wake is also discouraged, in order to prevent the crowding of people in closed spaces and the exposure of the deceased to an “open box”. What is contemplated is the following:

Prior to the transfer of the body, with a probable or confirmed cause of death by COVID.19, the personnel in charge and with medical criteria, may only authorize a direct relative and/or legal representative with authorization judicial (spouse, partner, children, parents), access to the isolation room in the hospital environment [...] All physical contact with the body and/or material surfaces that were around them is prohibited “. (MSGCABA: 6)

It is necessary to clarify that, before these recommendations were made public, most of the country’s funeral companies had already implemented some prevention measures, which included precisely the limitation of the assistance offered to relatives in relation to funerals and other honors.¹³ We were able to verify this from a partial survey of the institutional portals that these companies have on the Internet. In order to conduct the search and make the

¹² In relation to the religious precepts on the fate of human remains, the controversy generated by the cremation, by prescription of the health authorities of the Province of Chaco, of a member of the Jewish community, in the framework of the pandemic of coronavirus disease. For more details, consult the article “Creation controversy unleashes the first Jewish deceased by COVID-19 in Argentina” (Jewish Link, 03/29/20). Available at: <https://www.enlacejudio.com/2020/03/29/desata-controversia-cremacion-del-primer-judio-fallecido-por-covid-19-en-argentina/>.

¹³ The reason for the early adoption of these internal provisions had to do, among other things, with the contagion registered in a burial house in the San Martín district (Greater Buenos Aires). The incident occurred at the beginning of April, when the funeral home received the body of a woman from a health center. Those responsible for it allegedly omitted the true causes of death (which led to a criminal case for negligence). As a result, two funeral agents were infected, as well as relatives of the deceased and clinic staff. For more information, visit the following portal web: www.filo.news/actualidad/Duenos-de-una-cocheria-se-contagiaron-de-coronavirus-de-un-cuerpo-infectado-20200417-0003.html

systematization of the information more operational, we decided to limit the survey to those firms that are part of the “Argentine Federation of Funeral and Related Services Entities” (Fadedsfya)¹⁴. Of the total number of web pages (56), we found a dozen burial houses that inform the public about the preventive measures they have taken as a result of the pandemic. Let’s look at some examples:

The Parque San Agustín company, which has branches in various towns in Tucumán, accompanies the notice of closure of its offices with the slogan “In the distance closer than ever”¹⁵. For its part, the San Bernardo Sepelios company¹⁶, located in the same province, shares a series of recommendations on how to deal with grief in isolation. To mention only one of them:

Recommendations for the care of the bereavement of the quarantined child [...] since in that case the children will not have the opportunity to visit [their grandfather or grandmother], or to show them affection such as kisses or hugs [...] it is recommended that parents suggest that their children write a letter, send a message or make video calls by phone to a loved one who is ill, to alleviate to a certain extent the impossibility of offering them signs of affection in person [...] given the impossibility of celebrating funeral rites due to confinement measures [parents are recommended] to propose to the child to carry out some symbolic activity [...] such as drawing a picture, writing a letter or choosing a photograph of themselves ...

At the regional level, the impact of the health crisis has intensified. The scenes of bodies scattered through the streets of Guayaquil, of mass burials in the Vila Formosa de San Pablo cemetery (the largest in Latin America), or of the “humanitarian command for the removal of corpses” that daily travel the streets of Lima, corroborate the diagnosis made by the World Health Organization in May, regarding that “South America has become a new epicenter of the coronavirus”¹⁷. Therefore, it is not surprising that most countries are limiting all types of public acts, and funerals are no exception. The measures have been so rigorous - and their emotional consequences so damaging - that the Inter-American Commission on Human Rights (IACHR) released a statement the same month urging OAS member states to “respect and guarantee the rights of relatives of those who died in the framework of the COVID-19 pandemic, allow mortuary rites in a manner appropriate to the circumstances and, with this, contribute to the preservation of their memory and tribute.”¹⁸

A DIGNIFIED AND IRREVERENT DEATH

In Argentina, the norms of hospital confinement and the restriction of funerals soon caused discomfort among the families of the infected, health and funeral agents and other actors involved. Consequently, a series of protocols began to be implemented to guarantee the final accompaniment and farewell. For example, we can cite the initiative that the Rodolfo Rossi Hospital of the City of La Plata (Buenos Aires) carried out in June, called “Die

¹⁴ The other organization that completes the national picture is the “Argentine Federation of Funeral Associations” (Fadaf). Website: www.fadaf.org.ar.

accompanied”¹⁹. It guarantees that a family member accompanies a terminal patient with coronavirus. The interesting thing is that, in its foundations, this program affirms that “dying in company can be in itself a palliative act”.

In a similar direction, at the end of August the Legislature of the City of Buenos Aires approved a law that contemplates “the right to the last goodbye”, being the first jurisdiction in the country to sanction a measure with these characteristics. Among other concessions, it enables a person “from the affective environment of the patient to go to the hospital and facilitate, with a mobile device, communication with the rest of the family or relatives of the patient.” Days later, the Ministry of Health published the corresponding protocol for the implementation of the law. Among its provisions, it specifies that “the companion may carry objects” of emotional value to the patient, such as photos or letters.

At the national level, the health authorities released, also in August, a set of “recommendations” not only to allow the affective bond in these critical circumstances, but also the “interdisciplinary” containment of the patient’s family ²⁰. And they are recommendations because they address the particularities that a dismissal situation entails, in accordance with the availability of medical and psychological staff, beds, supplies, etc., but also deal with the specific emotional needs of each family; these are aspects that protocols tend to omit, argue the authors of the regulation.

In these examples becomes evident, once again, the centrality that the problem of what we call death acquires *in absentia* and how technological devices are considered as a valid alternative to manage the affective damages of separation. Even so, co-presence is an essential requirement to go through these final instances in the least traumatic way possible, as suggested by the aforementioned regulations, regarding containment between the bereaved, relatives and palliativists. Now, what has come to update the confinement of the dying and the estrangement from the deceased - whose bodies have now become vectors of contagion - is the discussion about the “good death” and the “bad death”. In line with what was stated by Laura Marina Panizo and Valérie Robin Azevedo (2020), we consider that the difference between both dimensions is determined not only by the causes of death, but also by the treatment given to those bodies. And the decisions made in this regard will result in a lesser or greater “pathologization” of the grief, depending on the case. Hence, those who call for the relaxation of sanitary restrictions, appeal with recurrence to the dignity of the victims of contagion and their right to be cremated in the most “humane” way possible. In this context, dignified death appears to be associated less with the claim of orthothanasia, than with the recognition of the right to jointly experience such a disturbing outcome.

At the same time that these demands acquired public status, social networks continued to be populated with countless content referring to the social emergency and its multiple effects. From testimonies of those who were directly or indirectly affected by the disease and the consequent preventive measures, to events of global impact from the four cardinal points, passing through the increasingly sophisticated *fake news*; all this production and circulation of

information has also caused the sensations, perceptions and emotions related to dying and death to be challenged with unusual assiduity.

If we conceive, as Scribano and Lisdero (2018) do, that looking/showing/feeling and receiving/sharing in and through networks suppose specific ways of elaborating perceptions - and that the latter are related to affective regimes and management of sensations mediated by ICTs-, then we can recognize the importance of the question of the way in which sensibilities are structured in virtual environments. And exchanges on fatality in times of pandemic are a good starting point.

Among the profuse material in this regard, perhaps the most viralized content (worth the term) so far is the one that has as its central theme the ballad of the Ghanaian *pallbearers*: a charismatic group of funeral directors, whose jovial choreography (edited together with a catchy identifying melody) would have sufficient ductility to adapt to any risky situation –real or apparent– that arose; including, of course, the contagion of viral disease. Such has been the popularity of this meme, that it was even used for different prevention campaigns in various countries. To mention a few cases: the Republican National Guard of Portugal shared on its official account *Facebook* a photomontage in which a poster with the African protagonists appears, accompanied by the following warning: “Stay home or dance with them! What do you prefer?”²¹. Just published, the post was shared more than 2,000 times and received hundreds of comments.

The Colombian National Police, for its part, recorded a video in which they emulate that choreography, to raise awareness of the importance of confinement to the inhabitants of Quibdó (Department of Chocó)²².

The curious thing about this phenomenon is the carefree and cheerful character with which the current crisis is approached, perhaps as a way of warding off the misery, fear and anguish caused by the daily verification of the mortality and lethality rates of COVID- 19. From our perspective, this palliative vocation would correspond to a type of affective regime with a certain preponderance in the present mediated interactions. Likewise, we suppose that the “irreverent” way of behaving in the face of dying and death in the context of a pandemic is stressed by other logics of feeling/wanting: those associated with the claim for the right to dignified treatment, dismissal and separation, which develop above.

CONCLUSION

Throughout these pages we try to reflect on the specificities, in our opinion the most relevant, that suffering/perishing acquires in the context of the current health crisis. In this sense, we base our approach on the perspective of a sociology of bodies/emotions, with the emphasis placed on the structuring of present sensibilities. The impossibility of referring to conclusive information on a phenomenon still in progress - and which, due to its magnitude and nature, does not have any contemporary referentiality either - made us go back to the Spanish Flu (1918-1920) and the corresponding hygienic measures adopted. Specifically, we

²¹ To read more about it, go to: <https://www.farodevigo.es/mundo/2020/04/17/africanos-ataud-secreto-mejor-guardado/2277242.html>.

considered how the management of corpses at that time configured an unprecedented “body geometry”, heralding a practice of distancing that today acquires the status of what we have called “death in *absentia*”.

And it is precisely this reconfiguration of the links between the bereaved/deceased and the social environment that has influenced the tensions between different “affective regimes”, which gain visibility on at least two levels: a) the regulations relating to hospital and funeral procedures, and b) the “management of sensations” in and through the networks, around the treatment of death in the times of coronavirus.

Ultimately, what it is about is a tragic event that has come to question, perhaps as never before, that politics of bodies and emotions that made the disturbing “tangibility” of the perishable more bearable.

The pandemic causes human beings to die alone; poor, rich, of all and various genders, of all ethnic groups, as in all dimensions of social structuring, the pandemic operates as a magnifying glass on the contemporary global structure: it isolates. It is precisely in the gale of volatility that death installs where the world has had to cling to love beyond all the discredit that colonial/patriarchal reason throws on that energy that breaks isolation and is therefore dangerous.

Chapter 499

CHILDREN, YOUTH, VIOLENCE, PUBLIC HEALTH AND MEXICO

Carolina de la Portilla and Enrique Cifuentes*, MD, PhD

Harvard School of Public Health, Boston, Massachusetts, USA

ABSTRACT

Violence is a public health concern that since 1996 has also concerned the World Health Organization. The study of violence from a public health perspective complements existing approaches (mainly from the criminal justice areas) by focusing on prevention through the identification of risk factors. The objective of this study is to address the rising levels of adolescent homicides in Mexico for the past 13 years (2000-2012) employing a socio-ecological framework, while attempting to identify patterns, temporal trends and corresponding risk factors. We confirmed that the rates of homicides among males aged 15 to 24 years old doubled between 2008 and 2010. Available evidence clearly indicates that the rise of the violent deaths curve, however, starts in younger groups. Our data also suggest that young males are much more likely to be homicide victims than females. Public health practitioners, teachers and advocates need to be more actively engaged in violence prevention activities. At the community level, potential interventions include slum upgrading, schools renewal programs and pacification projects, support for social cohesion and neighborhood policing in at risk or hot spots neighborhoods. We may face an ethical dilemma, and raise awareness to break the cycle or remain silent on these challenges.

INTRODUCTION

Violence results in more than 1.6 million people being killed each year globally with interpersonal violence as a major factor (1). Many more people suffer from sequelae of non-fatal intentional injuries, including disability, mental disease and chronic ill health (2). In

* Corresponding Author's Email: ecifuent@hsph.harvard.edu.

South Africa interpersonal violence is estimated to cause around 1.0 million (6.5% of all) disability adjusted life years (DALYs) (3).

The World Health Assembly first declared violence a major public health problem in 1996. The study of violence from a public health perspective complements existing approaches (mainly from the criminal justice areas) by focusing on prevention through the identification of risk factors (4, 5). This approach has gained considerable traction since the release of the first World Report on Violence and Health by the World Health Organization in 2002, which indicated that at least 85% of homicides were recorded in developing countries. The same report estimated between 73,000 and 90,000 firearms deaths annually in Latin America, three times the world average (6); most of these homicides occurred in Honduras, Guatemala, Salvador, Brazil, Venezuela, Colombia, Mexico, as well as Puerto Rico, Haiti and the Dominican Republic, from the Caribbean. Regional proximity to the highly profitable drug market in the United States has contributed to the existence of criminal organizations (7), which have thrived in recent years aided by high levels of political corruption, impunity, growing social inequalities and a steady flow of illegal guns smuggled from the United States to the South (8).

The epidemic of violence In Mexico has attracted attention in recent years. The government strategy implemented since 2006, namely the war on drugs and Merida initiative, was to mobilize the federal security forces in a declared military operation against the drug cartels and criminal organizations (9). Despite the deployment, the homicide rate in this country increased from 8.2 to 23.4 per 100 000 population between the years 2007 and 2012. By 2010 interpersonal violence was the number one cause of death among Mexican youth aged 15 to 24 years, and number three among those aged 10 to 14 years (10).

Children and adolescents, in particular, are now growing up in an environment characterized by threat of becoming a witness or a victim to a violent act, which can be detrimental to their physical and mental health. Available evidence suggests a relationship between early exposure to violence and an increased likelihood of aggressive and violent behavior later in life (11). For some scholars, the probability of adolescents becoming perpetrators of violent or unlawful acts and therefore the increased likelihood of being murdered can be further explained by using a socio-ecological framework (12) (see Figure 1). This framework covers four different levels of an adolescent's life: individual, family/relational, school/community and societal context, all of which may be critical in identifying potential risk and protective factors for the development of evidence-based violence prevention strategies and the use of public health tools. Health policy requires not only a clear understanding of different expressions of violence (e.g., domestic, gangs, armed conflict), and the complex driving forces of this epidemic's local determinants, but also the translation of knowledge from many disciplines into human rights protection and a stronger public health framework.

The socio-ecological framework (see Figure 1) has the following components:

- Individual level (e.g., biological factors, demographic characteristics', social and racial background; substance use)
- Interpersonal level (relationship to family and friends, social capital, gang involvement)
- Community level (Neighborhood); crime rates and safety issues,

Figure 1. Ecological model of risk factors (12).

- Society level (e.g., acceptability of violence and cultural values e.g., machismo, concerning availability of guns, gangs, police corruption and weak legal framework.

The objective of this study is to address the rising levels of adolescent homicides in Mexico for the past 13 years (2000-2012) employing a socio-ecological framework, while attempting to identify patterns, temporal trends and corresponding risk factors. We will also address the potential implications of our findings for the development of a stronger public health framework aimed at violence prevention. Our research questions were:

- Which factors contribute to the increased likelihood of adolescents becoming homicide victims?
- Which factors contribute to regional variability of homicides across the country?
- How do we translate knowledge into evidence-based prevention?
- Why do we need evidence-based prevention policy?

LITERATURE SEARCH

We conducted extensive literature searches using MEDLINE, JSTOR and HOLLIS. The purpose was also to outline potential research gaps and add them to our discussion. Search terms included interpersonal violence (intentional homicide, intentional injury, violent crime, aggression, violent behavior, child maltreatment, youth, abuse; injury surveillance, distribution of fatal violence, non-fatal violence, conflict; risk factors, epidemiology, ecologic framework, social inequality, child, youth, poverty, gun control, income inequality, early childhood exposure. Then we focused on Latin America, particularly Colombia, Brazil, Venezuela, Honduras, El Salvador; and Mexico, particularly US border (e.g., Ciudad Juarez in Chihuahua and Northwest); violence outcome, such as physical injury, mortality, mental health, aggression, PTSD, depression, stress, victimization/, violence prevention, such as prevention, school programs, crime prevention, urban development, public-health approach.

Research papers were organized according to relevancy and methodology employed.

We employed a socio-ecological framework aimed at organizing the multiple risk factors associated with the occurrence of violence (see Figure 1), while assessing regional and temporal trends in homicide rates in Mexico. We selected a time frame of 10 years (2002-2012), which includes four years prior the all out ‘war on drugs’.

We collected data from the public database of the National Institute of Statistics (INEGI) (13) and the National Council of Population Demographics (CONAPO) (14) to calculate the incidence of death rates due to intentional homicide across the country. Homicide rates were calculated for each gender and two different age groups. The homicide rate was calculated as follows:

$$\text{Homicide rate} = x_{(i, j)} / 100\,000 (\text{pop})_{(k, j)}$$

with the following components as i: Number of homicides in the state, j: age group and k: Population in the state. Homicide rates were calculated for each gender and two different age groups: 0 to 14 years old and 15 to 24 years old.

Eight geographical regions in Mexico were defined (see Table 1). Maps were created to better represent the regional differences, for which we further employed a geographical categorization for subsequent analysis.

To test the association between homicide and income inequality we used the GINI coefficient which is a measure of statistical dispersion intended to represent the income distribution of a nation's residents and is the most commonly used measure of inequality. The GINI coefficient for each federal state ($n = 32$) was collected from the public database of the National Council of Policy Evaluation and Social Development (CONEVAL) (15). We proceeded to use multiple regression methods to assess associations between homicide indicator and socio-economic indicators, which included the following:

- The average median income (median of the income distribution of heads of household)
- Population density (The logarithm was used as a variance-controlling transformation)
- Illiteracy rate (% of the population over 15, who cannot read or write)
- Percentage of the population aged 19 to 25 that does not work or study (NINI)

Table 1. Geographical sub-regions of Mexico

Sub-region	States
Northwest	Baja California, Baja California Sur, Chihuahua, Durango, Sinaloa, Sonora
Northeast	Coahuila, Nuevo León, Tamaulipas
West	Colima, Nayarit, Michoacán, Jalisco
North-central	Aguascalientes, Querétaro, San Luis Potosí, Zacatecas
South-central	Mexico city, Mexico, Morelos
East	Hidalgo, Tlaxcala, Puebla, Veracruz
Southwest	Guerrero, Oaxaca, Chiapas
Southeast	Campeche, Quintana Roo, Tabasco, Yucatán

The average median income-indicator was collected from the INEGI database (13), all other indicators were extracted from the CONEVAL database (14).

Statistical analysis, models, graphs and maps were done using statistical software (SAS 9.3. and JMP), using the SAS license provided by the LMU and the JMP license for students of the Harvard School of Public Health.

FINDINGS

Homicide rates in Mexico for adults showed a downward trend between 2002 and 2006. This trend, however, changed after 2006, when homicide rates started to increase and our data suggests that the younger age groups were affected as well (see Figure 2). There were a total of 24,272 homicides victims aged 0 to 24 years old between 2002 and 2012.

Figure 2. Average national homicide rates from 2002 to 2012 for age groups a) 0 to 14 and b) 15 to 24.

Homicide rates were calculated for the 32 federal states. The results showed great regional variability. Between 2002 and 2008, violence was mostly concentrated in the Northwest (NW) region of the country including Chihuahua, Durango, Sinaloa, Sonora and Baja California; violent deaths rates in the West (W) Central-north (CN) and Central-south (CS) regions had been declining during that period. Since 2008, however, homicides took a drastic turn and have since continuously increased. Regions the northeastern (NE) states of Tamaulipas, Coahuila and Nuevo Leon have experienced a drastic increase in homicides. The Southwest (SW) state of Guerrero also has extremely high levels of violence,

Yet it is important to note that two regions have not been as affected by high levels of interpersonal violence. The East (E) and Southeast (SE) regions remained the least violent throughout the analyzed time frame. Chiapas and Oaxaca, for example, do not have similarly high homicide rates.

Figure 3. Average homicide rates from male and females aged 15 to 24 years old for each geographical sub-region.

The male homicide rate for 15 to 24 year old increased significantly from 24,6 in 2006 and to 170,17 in 2010 (nearly 7 x higher). The rates of homicides for males from this age group doubled between 2008 and 2010 (from 26.6 per 100,000 to 52.06 in 100,000). The female homicide rate also grew 2.05 times in the same period.

The male homicide rate was consistently higher than the female rate in both age groups. Gender differences are more apparent in the older age group where male rates were between 6.17 and 8.96 times higher than female rates (see Table 2).

Table 2. National male to female ratio of homicide rates per 100 000 population for two age groups, 0 to 14 years old and 15 to 24 years old

Year	Ratio of male to female homicide rates 0-14 years old	Ratio of male to female homicide rates 15-24 years old
2002	1.53: 1	7.41: 1
2004	1.5: 1	6.17: 1
2006	1.54: 1	6.61: 1
2008	1.35: 1	8.96: 1
2010	1.4: 1	8.58: 1
2012	1.89: 1	7.76: 1

The Pearson correlation coefficient was employed to test the relation between homicide indicator and income inequality as measured by the GINI index (see Table 3). There appears to be an inverse correlation between the two variables, but the results were not statistically significant. Income inequality, as measured by the GINI coefficient does not appear to correlate with the homicide indicator on this geographical level.

The analysis between homicide rates and multiple socio-economic indicators was carried out using multiple linear regressions and the stepwise backward process. No significant correlation ($p < 0.05$) could be observed when other socio-economic indicators were

included, e.g., average median income, population density, % of the population aged 19 to 25 years that does not work or study and literacy rate.

We also constructed a second model, with each geographical region categorized by a dummy-variable, related to its location (see Table 4) e.g., proximity to the border with the USA (i.e., strong cartel presence and history of conflict), it receives the numeric variable 3.5; by contrast, the Southeast receives 0.5 (continuously the least violent region in the country).

Table 3. Correlation between the homicide indicator and the GINI coefficient

Variable by Variable	Correlation	Significance Probability
Homicide rate by GINI	-01152	0.53 ($p > 0.05$)

Table 4. Geographical sub-regions of Mexico and regional categorization (dummy variable)

Sub-region	Dummy-Variable	States
Northwest	3.5	Baja California, Baja California Sur, Chihuahua, Durango, Sinaloa, Sonora
Northeast	3	Coahuila, Nuevo León, Tamaulipas
West	2.5	Colima, Nayarit, Michoacán, Jalisco
North-central	2	Aguascalientes, Querétaro, San Luis Potosí, Zacatecas
South-central	2	Mexico city, Mexico, Morelos
East	1.5	Hidalgo, Tlaxcala, Puebla, Veracruz
Southwest	1	Guerrero, Oaxaca, Chiapas
Southeast	0.5	Campeche, Quintana Roo, Tabasco, Yucatán

Table 5. Regression results for regional categorization of 8 sub-regions and homicide indicator

Parameter	Estimate	Std. Error	Significance
Intercept	-43.13	31.56	0.18
Regional category	48.29	13.75	0.0014 *
R ² adjusted	0.267		

Table 5 shows our results, which suggest that this categorization could be used as predictor for homicides across the country, accounting for 26.7% of the total variance in the homicide indicator. It could prove useful for the development of interventions strategies and allocation of resources and funds in priority regions, i.e., where young people may be at risk.

DISCUSSION

This study was aimed at producing preliminary data describing links between violence, particularly interpersonal violence, and some factors contributing to the increased likelihood of young individuals, including adolescents and children, becoming homicide victims or perpetrators. Further questions concerning social, economical, geographic and temporal variability of violent deaths across the country were also addressed in this investigation. The

magnitude of the epidemics, as our data show, reflects an urgent need to break the cycle of violence with prevention measures and public health interventions targeting the youngest groups of the population.

We confirmed that the rates of homicides among males aged 15 to 24 years old doubled between 2008 and 2010. Available evidence clearly indicates that the rise of the violent deaths curve, however, starts in younger groups. Our data also suggest that young males are much more likely to be homicide victims than females. We observed, however, that women are increasingly involved in violence related episodes. Similar trends were reported by Krug et al. (1).

Our approach allowed us to observe temporal and geographical patterns of violence outbreaks. We simply used the “ecological model” to assess the risk of violent deaths at different levels of analysis, i.e., from the individual to the region.

Data clearly indicates that homicide rates increased seven times between the years 2006-2010, reflecting deadly conflict among organized crime groups fighting for territories and control over routes for smuggling illegal drugs, firearms, humans and enormous criminal profits. This was particularly the case near the Mexico-US border. To our knowledge, this investigation provides original evidence of the effects of violence on the youngest groups in Mexico during the full blown of the war on drugs.

We failed to observe statistical associations between the rates of homicides and income inequality, as measured by the GINI coefficient, and the homicide indicator did not appear to correlate with other socioeconomic indicators used in this investigation. This is, indeed, a clear reflection of the limitations of the ecological method. It is necessary to point out that this investigation, however, does not pretend to show causal associations, but to contribute to the debate on the lessons from recent failures (e.g., the consequences of the war on drugs), while sharing experiences concerning what works and does not with other countries suffering similar outbreaks of violence.

The epidemics of violence in Mexico represent a complex and deeply rooted social and political disorder, for which there are no simple solutions. It may be suggested, however, that major risk factors contributing to the increased likelihood of adolescents becoming homicide victims and perpetrators need to be targeted and prevented. Children and youth, in particular, need to be protected from violent events and becoming witnesses or victims of violent acts. Available evidence suggests a relationship between early exposure to violence and an increased likelihood of aggressive and violent behavior later in life (11).

From a macro-level perspective, governance instruments need to be upgraded to reduce substantially illegal profits from the drug market, impunity and political corruption, as well as the steady flow of deadly guns smuggled from the United States to the South, all of which has contributed to the existence of criminal international organizations (7, 8). These organizations recruit youth for their illegal operations; lack of better options (e.g., jobs, higher education) may push young individuals into violence and homicide.

Furthermore, corruption at all levels has significantly impacted education (16, 17) and without an educated population, it becomes difficult to offer or create jobs resulting in high unemployment or underemployment thus resulting in the temptation to engage in activities that offer money with action, regardless of the price that has to be paid in the loss of lives – one’s own or another’s’. This chronic state of poor education resulting in unemployment has also resulted in the large migration of people to the north, to the US and its promises of

success – financial and educational; thus choosing a better life for themselves and their children (18).

Public health practitioners, teachers and advocates need to be more actively engaged in violence prevention activities. At the community level, potential interventions include slum upgrading, schools renewal programs and pacification projects, support for social cohesion and neighborhood policing in at risk or hot spots neighborhoods. We may face an ethical dilemma, and raise awareness to break the cycle or remain silent on these challenges.

Chapter 500

LAW ENFORCEMENT AND PUBLIC HEALTH: HOW NORTH CAROLINA BECAME A LEADER IN HARM REDUCTION POLICY CHANGE

ABSTRACT

Fatalities from accidental drug overdose are endemic across the country and have risen to epidemic levels. To curb this epidemic, several states including North Carolina have recently adopted new laws or practices to help reduce the rates of accidental overdose. This chapter focuses on the development and implementation of two harm reduction laws that passed in the 2013 legislative session in North Carolina, a Southern state with a political and social climate traditionally resistant to harm reduction pragmatism. Analysis is offered as to how these laws were successfully championed by harm reduction advocates, Republican sponsors, and with the support of law enforcement associations. Additionally, preliminary data on a study to train law enforcement officers on these new policies is presented. North Carolina's ability to pass and promote these two laws serves as a guide for how other jurisdictions can be successful in promoting pragmatic policies despite steep opposition to traditional harm reduction principles.

Keywords: policy change, Good Samaritan laws, overdose prevention, decriminalization, law enforcement

INTRODUCTION

Fatalities from accidental drug overdose are endemic across the country and have risen to epidemic levels. The burden of drug-related overdose deaths has been well documented (Warner, Chen, Makuc, Anderson, & Minino, 2011) and some studies have shown that more than 90% of unintentional poisoning deaths in the United States involve drugs (Paulozzi, Budnitz, & Xi, 2006). Nationwide, overdose has surpassed auto vehicle fatalities as the leading cause of accidental death (Centers for Disease Control [CDC], 2013). In North Carolina, overdose rates have tripled since 2000 (CDC, 2013). The number of fatal poisonings in 2011 claimed 1,368 lives, with 91% of these deaths classified as drug overdoses, primarily due to opioid analgesics (Harmon, Proescholdbell, Marshall, & Waller, 2014; North Carolina Injury and Violence Prevention Branch, 2013).

To curb this epidemic, several states have adopted new laws or practices to help reduce rates of accidental overdose. For example, most states have passed so-called “Good Samaritan” laws intended to encourage victims or witnesses of drug overdoses to seek medical assistance by providing varying levels of immunity from drug-related criminal charges (Davis, Webb, & Burris, 2013). In addition, nearly 40 states have modified laws to increase access to naloxone (commonly known by its trade name, Narcan), a prescription medication that blocks the effects of opiates and reverses an opioid overdose (Beletsky et al., 2007; Coffin & Sullivan, 2013). While naloxone does require a prescription, it can also be what is called “a third party prescription” or standing order given to others by a health professional who has prescribing privileges (Davis, 2015).

Naloxone access has been described as “one of the most promising interventions to date” (Dasgupta, Sanford, Albert, & Brason, 2010, p. 4). The combination of improved access to naloxone, coupled with educating family and friends on how to recognize and respond to the symptoms of overdose, has been credited with preventing overdose deaths for thousands of individuals in the United States (Dasgupta et al., 2010). Despite increased efforts to improve access to naloxone and other evidence-based interventions (Coffin & Sullivan, 2013; Green, Heimer, & Grau, 2008), opiate overdose remains a major public health concern across the United States, and particularly in North Carolina (CDC, 2013; Davis & The Network for Public Health Law, 2015).

This chapter is guided by a three-fold purpose. First, the chapter outlines the political and social context of laws passed in North Carolina during 2013 to promote public health, specifically the health of those who use drugs, those at risk for overdose, and the people with whom active drug users interact. Second, this chapter describes a campaign to create public health laws that incorporate a harm reduction approach to overdose and the prevention of blood-borne diseases, despite resistance to this approach in a conservative Southern state. The specific legislation discussed includes a needlestick prevention law (HB850: Possession of Needles/Tell Law Officer) and the Good Samaritan/Naloxone Access (SB20) law. Third, this chapter presents data from a 2013-2014 law enforcement officer training designed to educate officers on these two laws. Overall, this chapter focuses on the implementation of these two harm reduction laws and offers an analysis of how these laws were passed in North Carolina, a Southern state with a political and social climate traditionally resistant to harm reduction pragmatism.

Harm Reduction: Policy and Methodological Challenges

Harm reduction policy, as defined by Marlatt and Witkiewitz (2010, p. 595), “seeks to meet individuals where they are and provide assistance with helping individuals and communities reduce the harms associated with drug use and other risky behaviors.” As previously described in this book, programs and policies based on a harm reduction approach are often met with opposition for a variety of reasons. Some of the most commonly cited objections to harm reduction approaches include opponents’ belief that this approach gives individuals permission to continue engaging in harmful and illegal behaviours, that harm reduction enables users, and that a harm reduction approach sends a mixed message to youth about substance use being condoned (Marlatt & Witkiewitz, 2010).

Inherently, the social and health problems that public policies attempt to alleviate are complex, difficult to understand, discuss, and reconcile. First, methodologically, policies related to harm reduction touch on core societal conundrums (e.g., equality, fairness, personal responsibility, and role of government) with little agreement as to the best solution. These types of problems are “thorny” in nature (Bogenschneider & Corbett, 2010, p. 8), and have been described as “wicked problems” (Rittel & Melvin, 1973) because they involve emotional, complex, and debatable components that can seldom be analyzed in isolation. Drug policies and their related social and health consequences are complicated and perplexing. Put simply, wicked problems such as drug use are often symptoms of other problems, which are never fully solved, and policies related to these wicked problems have no immediate test of effectiveness. Even when evidence is available to guide policy decisions, such as with syringe access programs, policy in this arena is often based on morality, authority, and ideology (Zerden, O’Quinn, & Davis, 2015). This dismissal of evidence is particularly true regarding programs designed for vulnerable population groups such as those with substance use disorders and those at risk for HIV/AIDS and other blood-borne pathogens (Zerden et al., 2015).

Why Policy Is Needed to Reduce Overdose Fatalities

Numerous social, economic, and emotional costs are associated with drug overdose. The most salient factor is that expanded access to opioid overdose prevention saves lives. High doses of opiates (or opiates in conjunction with other substances) depress the central nervous system, and can lead to respiratory failure and death. However, most opioid overdoses are reversible if naloxone is given before the person stops breathing and suffers irreparable harm from the lack of oxygen (Davidson, Ochoa, Hahn, Evans, & Moss, 2002; Green et al., 2008). Several studies have shown that more than half of drug overdoses occur in the presence of at least one other person, but witnesses often do not seek emergency help for the victim out of fear of criminal consequences for themselves or the victim (Tracy et al., 2005). Despite the effectiveness and safety of naloxone in reversing overdose (Coffin & Sullivan, 2013; Kim, Irwin, & Khoshnood, 2009; Walley et al., 2013), the number of fatal opiate overdoses has continued to rise in North Carolina. Further, the public is largely unaware of the use and effectiveness of naloxone to help prevent overdose fatalities.

North Carolina: Political Context

The North Carolina Legislature enacted two laws (HB850 and SB20) in 2013 as part of a statewide effort to reduce opiate overdose fatalities and to limit the penal consequences of drug use in cases of overdose (North Carolina General Assembly, 2013). The passage of these laws was remarkable because the bills were approved during a legislative session marred by a hostile social and political climate that was inhospitable to progressive policy priorities (Van der Horst, 2014). Harm reduction policy typically falls into the category of progressive policy, and therefore, proposals for harm reduction policies are most often met with a focus on abstinence and morality (Zerden et al., 2015). The political unrest and struggle for social justice around several issues in North Carolina garnered national attention due to strong partisan divisions and statewide protests, which became nationally known as “Moral Monday” protests. The Moral Monday protests were:

... carefully planned by a broad coalition of North Carolinians, including environmentalists, voting-rights advocates, leaders in reproductive health, educators, workers, and immigrants, all led by the North Carolina NAACP. The protest[s] were organized in the tradition of civil disobedience, whose history reaches back through Martin Luther King, Jr. and Mahatma Gandhi to Henry David Thoreau (Van der Horst, 2014, p. 1959).

Through unique partnerships with law enforcement and a statewide grassroots harm reduction coalition, these two laws were passed with near unanimous support in both the Senate and House of the North Carolina General Assembly. Despite the political tone of the 2013 legislative session, North Carolina became the first Republican-controlled state in the nation to pass a partial syringe decriminalization law (i.e., HB850: Needle Possession/Tell Law Officer) and a Good Samaritan/Naloxone Access law (SB20). As explained later in this chapter, North Carolina’s ability to pass and promote these two laws serves as a guide for how other jurisdictions can be successful in promoting pragmatic policies despite steep opposition to traditional harm reduction principles (Davis, Walley, & Bridger, 2015).

Legislative Advocacy: A Response to Overdose Fatalities in North Carolina

In the early 2000s, key stakeholders in North Carolina began focusing on the prevalence of the common causes of fatal injuries related to prescription drugs. These stakeholders included leading epidemiologists; public health practitioners and researchers from all sectors, including North Carolina’s Injury and Violence Prevention Branch; the Department of Health and Human Services; local health departments; overdose prevention groups, such as Project Lazarus; and grassroots advocacy organizations, including the North Carolina Harm Reduction Coalition (NCHRC). Advocacy by NCHRC, the State’s only comprehensive harm reduction organization, has been ongoing since the mid-2000s. The advocacy work of NCHRC is notable because the organization is small, with only three full-time employees. Nevertheless, during the 2012 North Carolina General Assembly legislative session, NCHRC staffers strategized with their board of directors on working toward legislative reforms related to overdose prevention while continuing the organization’s longstanding support for greater access to sterile syringes to reduce the spread of blood-borne disease.

As a result of these combined efforts, SB20 or the Good Samaritan/Naloxone Access bill, was first filed in the Senate on January 30, 2013. This bill was sponsored by two Republican State Senators and garnered bipartisan support. NCHRC first approached the Senators

through a presentation to the Child Fatality Task Force, a legislative committee designed to address child mortality and to make recommendations to reduce deaths. This Task Force recognized the rise of drug-related overdoses in the State. NCHRC attended the meeting accompanied by allied constituents who were directly impacted: North Carolinians who lost children or siblings to drug overdose. The personal testimonies of family members was pivotal in reaching the Senators and one commented in personal communication that “hearing the family speak of their loss was the most moving moment of [his] substantial legislative career.” These two State Senators together, with their many years in office, and with respect and support among their peers, were instrumental in obtaining bipartisan support for the bill and engaging law enforcement. Choosing the right sponsor is key to getting legislation passed. As one NCHRC staff member and a registered lobbyist explained, when meeting with legislators to advocate, knowing who sponsored the bill is often more important than the content being presented.

SB20 provides limited immunity for certain drug-related offenses for (a) individuals who seek medical assistance for a victim of an overdose, and (b) the victim of the overdose. In addition, the law provides immunity for practitioners who prescribe an opioid antagonist (e.g., naloxone) to a third party (e.g., a person who has close contact with someone at risk for drug overdose) and immunity for individuals who administer an opioid antagonist to a person experiencing an overdose. The goal of the law is to encourage people who might witness an overdose to summon emergency aid without fear that doing so will result in criminal justice repercussions (Center for Public Health Law, 2014) and to reduce drug-related fatalities by providing greater access to opioid antagonists.

Whereas SB20 focused on protections for those involved in an overdose situation, the second harm reduction law (HB850) focused on protecting law enforcement personnel. Under the provisions of HB850, if a person declares a needle or other sharp object to an officer prior to a search, that person cannot be charged or prosecuted for possession of drug paraphernalia. All primary sponsors were Republicans and the bill had 17 co-sponsors, including bipartisan support. NCHRC achieved this by approaching a Republican Representative who had previously served as Chief of Police for a community in High Point, North Carolina. As a former law enforcement officer, this Representative was sympathetic to the idea of helping officers avoid needle-stick injury from people carrying drug paraphernalia. This bill became a law enforcement safety issue and less focused on drug use - a reframe that helped make the issue more palatable. Representative also had connections with the Sheriffs Association and the North Carolina Association of Chiefs of Police. These groups worked with NCHRC directly to craft a bill that all parties could support. The final version of HB850 was substantially different from what NCHRC had initially proposed (e.g., full syringe decriminalization). However, as a harm reduction organization, NCHRC felt this was still considerable progress towards harm reduction policy that did not previously exist.

The lessons learned were once again, the importance of finding the right bill sponsors as well as reframing the issue to appeal to stakeholders on all sides. Often times, this means a person who is respected within the legislature, a member of the party in power, and someone who has positive relationships with powerful civic and community groups such as law enforcement associations. Additionally, NCHRC also demonstrated compromise by accepting a watered-down version of their original bill in order to move their organization’s policy agenda forward. This cooperative relationship has become an important feature of NCHRC’s

advocacy work in the State as they continue to pass follow-up legislation with these same sponsors.

Law Enforcement Officer Training and Harm Reduction Pragmatism

Once harm reduction policies are in place, the next step is to ensure that all stakeholders are informed of new laws and regulations. In this case, the next necessary step was to make sure law enforcement officers were aware of the provisions of the new laws recently passed. Implementing educational training to inform practitioners and law enforcement of practice and policy changes to increase awareness of opioid overdose and to prevent unintended death is supported within the literature (Compton, Volkow, Throckmorton, & Lurie, 2013). Moreover, the Office of National Drug Control Policy (2011) has included educational training on opioid overdose as part of their four-pronged strategy to reduce overdose fatalities. In the following section, we describe a law enforcement training project that was implemented in North Carolina to educate officers on the purpose and provisions of these two laws. This training is one example of an innovative and effective method of assessing officers' attitudes and knowledge regarding syringe decriminalization, overdose prevention, and HIV/AIDS or other blood-borne risk as an occupational hazard. In addition, the training provided officers with information regarding how the new state-level policies would directly affect vulnerable groups and individuals who interact with officers. This is particularly important in situations that are likely to be adversarial - such as arrests for drug violations.

Due to current U.S. laws, law enforcement plays a role in how social and health policies are implemented given their involvement with people using/involved in illicit drug use and other risky behaviours (e. g., sex-work, sharing needles) (Beletsky, Macalino, & Burris, 2005; Davis & Beletsky, 2009). Law enforcement officers themselves can be exposed to blood-borne pathogens through occupational risks, including the potential for needlesticks during routine pat-downs, or contact with bodily fluids while providing CPR or taking suspects into custody (Schwerha, 2004). However, the limited available research on the intersection of law enforcement and HIV/AIDS risk has demonstrated that misconceptions and myths exist, as Davis and Beletsky (2009, p. 2) noted:

Officers express significant anxiety about these risks, [but] typically have limited access to training and resources that can equip them to effectively reduce the risks and to navigate the complex set of mental health, addiction and other issues pervasive among injection drug users and other marginalized populations.

The combination of anxiety and lack of training can lead to miscommunication and apprehension between officers and those they encounter on the streets. This same dynamic can exist for officers in overdose cases, especially because officers are often the first at the scene. Equipping these professionals with naloxone could improve overdose outcomes by reducing the response time to treatment and can possibly save lives (Davis, Ruiz, Glynn, Picariello, & Walley, 2014). Yet like attitudes about occupational hazards, little is known about officers' attitudes regarding naloxone access or officers' attitudes about administering naloxone to overdose victims. Prior to the authors' previous study on North Carolina law enforcement officers, no studies had examined officers' knowledge and attitudes around HIV/AIDS risk and overdose prevention in the Southeast United States. Research to better

understand these attitudes was a necessary step to guide efforts toward overcoming resistance and misunderstanding related to harm reduction programs and policies.

The following overview highlights Davis and colleagues' (2014) study that assessed the pre- and post-training attitudes of a cohort of 349 North Carolina law enforcement officers regarding syringe decriminalization, blood-borne risk perception, and recent policy changes around SB20 and HB50. In addition, the overview highlights the work of the NCHRC in partnership with statewide law enforcement groups that coordinate trainings for Crisis Intervention Teams (CIT), a specialized law enforcement certification. CITs use evidence-based approaches to interact with people who are experiencing acute mental health crises, with the aim of helping law enforcement officers deescalate the intensity of situations they encounter.

METHOD

Through connections made with a coordinator for the state-run CIT trainings, NCHRC was invited to provide a one hour-long training for officers working to become CIT certified. The CIT model is designed to improve the response of law enforcement and the community to people who are experiencing mental health crises (National Alliance on Mental Illness, 2013; Watson & Fulambarker, 2012). The training session was required for all officers seeking the CIT certification and included an overview of HIV transmission and other blood-borne diseases and instruction in ways officers could reduce their risk of on-the-job disease transmission. In addition, the training addressed the policy changes intended to reduce officers' risk of needlestick through syringe decriminalization. The NCHRC staff collected data on trainings provided in 2012 and 2013 to 349 officers from 20 law enforcement agencies throughout North Carolina (for a full description see Davis et al., 2014).

Data Collection

Data were collected via a voluntary, anonymous survey that participants completed before and after the training session. The survey instrument collected brief demographic data and queried participants regarding perceptions of their HIV risk and attitudes toward syringe decriminalization. All items used the same 4-point Likert-type response scale, with options of *strongly agree*, *agree*, *disagree*, and *strongly disagree*. Responses were then dichotomized into *agree* and *disagree* responses. Table 1 offers a brief description of the sample of officer participants. Descriptive statistics were compiled for each question and assessed by race (Black vs. non-Black), by gender (men vs. women), and age because the research team hypothesized that attitudinal differences may exist based on these demographic characteristics.

Table 1. Sample demographic characteristics of law enforcement officers (N = 349)

Characteristics	%
Gender	
Men	79.3
Women	20.7
Race/Ethnicity	
White	65.0
Black	25.5
Hispanic	4.6
Other	4.0
Asian	.9
Age (in years)	
20-29	26.4
30-39	32.2
40-49	31.3
50-59	9.0
60-69	1.2
Years in law enforcement	
< 7	
7-13	43.3
14-20	24.7
21-27	20.6
28 +	11.3

RESULTS

Although law enforcement respondents overwhelmingly reported that they feared contracting HIV on the job, only 3.8% (about 13 of 349 officers) of the sample reported ever receiving a job-related needlestick injury (Davis et al., 2014). About 42% of respondents agreed that statewide decriminalization would promote drug use, 59% said that their impression of syringe decriminalization was generally positive, with nearly 60% agreeing that decriminalization would reduce HIV transmission, be “good for the community” and “good for law enforcement.” Interestingly, both Black and women law enforcement officers were statistically significantly less likely to report that they feared contracting HIV on the job, and more likely to agree that decriminalization would be “good for the community” and “good for law enforcement.” Although the results of the study are discussed in greater detail in our earlier work, this chapter discusses the gender and racial/ethnic differences within the sample.

First, as compared with white male officers, Black and female officers held more realistic views of their risk of receiving an on-the-job needlestick injury, and held much more positive views of syringe decriminalization. This finding is especially important because white male officers comprised the majority of the sample and, although specific public data is not available, white male officers comprise the majority of law enforcement within North Carolina. Interestingly, the finding of racial and gender differences would not be predicted based on the available literature. A recent survey of law enforcement officers receiving drug interdiction training (i.e., covers all aspects of drug enforcement), reported few differences by

race or gender in trainees' attitudes toward drugs and drug enforcement (Poteyeva & Sun, 2009).

It is important to note that whereas Black respondents comprise only 22% of North Carolina's population, nearly 67% of the cumulative AIDS cases reported in North Carolina have been among Black residents (CDC, 2012; U.S. Census Bureau, 2012). Possibly, as a result of this disparity and frequency in which HIV/AIDS impacts the Black community in North Carolina, there was more awareness regarding these risks. Possibly, this disparity in HIV/AIDS prevalence may account for some of the variation in attitudes among Black and non-Black officers regarding decriminalization and fear of on-the-job infection.

In summary, the law enforcement officer training serves as an innovative community initiative to address the growing overdose epidemic by providing educational trainings, establishing key community relationships, and organizing ongoing educational opportunities at the state level.

CONCLUSION

According to the Drug Policy Alliance (2015):

The chance of surviving an overdose, like that of surviving a heart attack, depends greatly on how fast one receives medical assistance. Witnesses to heart attacks rarely think twice about calling 911, but witnesses to an overdose often hesitate to call for help or, in many cases, simply don't make the call.

NCHRC has recently encouraging law enforcement departments to carry and know how to administer naloxone as part of their role as first responders to emergency situations. To date, five police departments and one county Sheriff's Department in North Carolina have been trained in overdose prevention and carry naloxone for possible administration on the job. In addition, NCHRC has distributed more than 10,000 naloxone kits to those at risk for overdose and has recorded more than 1,000 rescues between 2013 and 2015.

The next step in assessing the effectiveness of these two harm reduction laws requires collecting and analyzing additional data. Analysis of hospital data are underway to review emergency room utilization for overdoses, as well as calls to emergency personnel (emergency medical technicians, firefighters, and police officers) in response to overdose, whether naloxone was available and used. Determining whether the two laws enacted in North Carolina have had an impact on public health to reduce the number of overdose fatalities is an important marker of lasting-impact and positive change. The answers to this remain unknown given that policy implementation is still relatively recent, yet harm reduction policy change was possible. This achievement seems noteworthy not only because of the social and political context of our Southern State, but also due to creative partnerships working together to curb the overdose epidemic in North Carolina.

Chapter 501

EXPANDING THE MISSION OF HARM REDUCTION: A PUBLIC HEALTH POPULATION AND ITS MEMBERS’ PERSPECTIVES TOWARDS HEALTH

Kelly Szott*

Earlham College, Richmond, Indiana, USA

ABSTRACT

Introduction: People who inject drugs became a bounded group in the United States when the Centers for Disease Control named them as a “high risk group” for AIDS in 1981. Since then, both grassroots activists and public health officials have worked to manage and regulate this group through discourses and practices affiliated with the term “harm reduction.” Using public health research literature and social scientific renderings of the history of the HIV/AIDS epidemic, this chapter begins by historically tracing the governing of the “injection drug user” risk categorization under the rubrics of public health noting how acts of subjectification placed the drug user in certain relationships to his or her health.

Methodology: Narratives of health within forty qualitative interviews with low-income people who inject drugs in New York City are examined noting convergences and divergences from conceptions of health mobilized by public health governmentality.

Results: Through public health research and practice in the 1980s, the health of people who inject drugs was intimately tied to HIV. This sustained a trajectory of research that constructed the “injection drug user” in ways that produced surfaces for the play of normalizing power. However, in qualitative interviews people who inject drugs did not often identify health concerns related to risk for HIV. Instead, this group was largely concerned with chronic health conditions caused and made worse by living in extreme poverty. In order to address this divergence, the harm reduction movement must expand its mission.

Keywords: stigma, governmentality, harm reduction, health, access to health care, qualitative interviews, phenomenology

INTRODUCTION

Previously considered a risk group for hepatitis B, “intravenous drug abusers”¹ began to receive increasing interest from public health researchers in the early 1980s when they were identified as an AIDS risk group. The “intravenous drug abuser” was subsequently produced and managed through scientific discourse and behavioural interventions. Grassroots activists responding to a crisis of illness among their family members and friends, began organizing underground efforts to provide syringes to enable and enjoin individuals to address their own risk for disease, as well as the risk of transmitting disease. These humanitarian efforts to produce knowledge and provide care were powerful operations that produced the subject of injection drug use. Following Deverteuil and Wilton (2009), acts of caring for individuals can be understood as forms of governance, whereby power works through enactments of care and protection and the promise of well-being. In organizing and containing the disorder, researchers and activists created an enduring categorization that would place people who use drugs by injection in particular relationships with their health and their bodies.

This chapter offers a rendering of this history of care and categorization as a way to understand the historical roots of an identity category mobilized by researchers and activists alike. Through research and activism affiliated with harm reduction, people who inject drugs were provided with education and material resources to address their risk(s) for HIV. Understanding the practices and politics of public health and harm reduction as productive of subjects who speak about their health in terms of risk (Campbell & Shaw, 2008; McLean, 2011; O’Malley, 1999), this chapter presents the self-described health concerns of a group of low-income people who inject drugs in New York City. Qualitative interviews were conducted with these individuals in 2012 and 2013 to learn if and how their articulations of health resonate with the set of health concerns mobilized by harm reduction policy (i.e., HIV, hepatitis C, and overdose). These narratives of health highlight convergences and divergences from the aims of public health governmentality.

BACKGROUND

Genealogy of a Risk Category

“... the ways in which these categorizations are made, and which categories come to have effects in the world, are never neutral.”

David Valentine (2007, p. 5)

Re-visioning the “injection drug user” as a socially constructed category beginning in the 1980s offers a penetrating reflection, in the mode of a Foucauldian (1997) genealogy, on the

¹ A note about language: There have been several terms used in the scientific literature to label people who inject drugs. The initial term that predominated was “intravenous drug abuser,” which was then changed in the late 1980s to “intravenous drug user” and very soon after to “injection drug user.” None of these changes were across the board; for example, some still use “intravenous drug user.” Recently, there has been a push among people who conduct research on injection drug use to use the term “people who inject drugs” because it represents people-centered language. In agreement with this change, I have attempted to use this language. However, when writing about older research, I use the terms employed by the authors and put them in quotes. Any inconsistency is a result of my own reticence to use this more stigmatizing language.

constructive acts of power, as it literally brings certain subjects into being on both a discursive and material level. This risk category was created as an act of governmentality by a diffuse set of actors labouring under a concern for managing a population and the individuals it contains. The Foucauldian concept of governmentality aids in understanding how power is exercised at both the level of the population and the level of the individual (Foucault, 2007). In governmentality, the sphere of the social is constituted by two types of power—policing at the population level and pastoral care at the level of the individual. These form the, “... double itinerary of a power that moves *between* managing social relations and governing individual conduct” (Orr, 2010, p. 549). The production of the drug-injecting subject through research activities involves an intersection of these two types of power, as efforts are made to regulate the population and individuals are activated to participate in self-care.

Using its risk group schematic, the Centers for Disease Control² (CDC) reported the first cases of AIDS among people who inject drugs in late 1981. The risk group organizational principle introduced more fully by the CDC in 1983 (Oppenheimer, 1988) served to make order out of the disorder generated by this new disease. By creating such a schematic the CDC contributed to an understanding of the disease that placed the onus of infection and transmission onto certain groups of people (e.g., homosexual men, drug injectors, Haitians, among others) regardless of whether they participated in practices that could lead to infection (Glick Schiller, Crystal, & Lewellen, 1994; Oppenheimer, 1988). Although the language of the risk group label has shifted over the last three decades, the categorization of people based on drug injection has persisted. This reveals that when supported by hegemonic systems of rationalization, which themselves are often undergirded by “stories,” there can be a “hardening of the categories” (Verran, 1998, p. 241).

When the CDC released its first report on AIDS, drug use researchers had been suspecting for several years that some type of ailment was impacting people who inject drugs as they were seeing a rising number of pneumonia-related deaths (Campbell & Spillane, 2009). Prior to AIDS, it was clear to public health workers and injectors alike that hepatitis B was spread through the sharing of needles. This knowledge was applied to the new condition, referred to as “walking pneumonia,” and injectors began to adjust their drug use practices (Campbell & Spillane, 2009; Des Jarlais, Friedman, & Hopkins, 1985). Beyond their association with hepatitis B, people who used drugs by injection had not received much attention as a coherent group by researchers. Most of the prominent social science literature on drug use before HIV/AIDS focused on the type of drug used or simply on “addicts” (e.g., Agar, 1973; Becker, 1963; Feldman, 1976; Preble & Casey, 1976). Beginning in 1984, “intravenous drug abusers” began to have a salient presence in public health research literature. Examining popular research articles reveals a process of construction and governance, as the person who injects drugs is surveilled, described, and subjected to behavioural interventions.³ The historical timeline offered here is broken into the following three, non-mutually exclusive eras of governance and construction: suspicions and concerns (1984-1985), surveillance and differentiation (1986), and behaviour change and self-advocacy (1987-1988).

² It was not until 1992 that this federal agency’s name became the Centers for Disease Control *and Prevention*.

³ This process was observed through the review of research publications similar to a typical literature review, except that older publications with relatively high citation numbers (as reported by Google Scholar) were specifically sought.

Suspensions and Concerns (1984-1985)

Articles published in 1984 and 1985 expressed conjectures about routes of transmission and concerns about containment of the virus. There was a common concern that AIDS could be spread from “IV drug abusers” through sex and perinatal transmission (Ginzburg, 1984; Marmor, Des Jarlais, Friedman, Lyden, & El-Sadr, 1984). This claim constructs the person who injects drugs as a vector in the spread of AIDS and also points to the necessity of containing the virus within this group. Intravenous drug users were identified as a “bridge” for the transmission of AIDS⁴ to other groups, most notably children and heterosexual partners (Des Jarlais et al., 1985, p. 98). This discursively constructs a boundary around this group placing them in opposition to two socially-sanctioned groups—non-injectors and children. In these early articles, researchers hesitantly proposed that AIDS was spread between injectors through the sharing of needles and other injection related materials (Ginzburg, 1984; Marmor et al., 1984). To further efforts aimed at managing the disease among people who inject, a call for a clearer definition of this community was made by a director at the National Institute of Drug Abuse (NIDA) in a 1984 publication (Ginzburg, 1984). These nascent ideas present pathways of intervention that demonstrate the early stirrings of governmentality by identifying a bounded group, highlighting individual-level, malleable behaviours such as the sharing of needles, and calling for the collection of more information about the group.

Surveillance and Differentiation (1986)

In 1986, literature based on ethnographic research began to appear that outlined the cultural traits of the “subculture” of people who inject drugs. As Campbell and Shaw (2008) write: “Ethnographic drug research has been a central discourse through which the construction of identity categories has metamorphosed into the IDU subject position” (p. 707). An air of hopelessness was present as researchers described the social bonding that needle sharing enabled among injectors (Des Jarlais, Friedman, & Strug, 1986; Friedman, Des Jarlais, & Sotharan, 1986). The sharing of works was described as a ritualistic part of the initiation into drug injection, a necessity and a way of demonstrating trust between sexual partners or friends (i.e., running partners), and an economic and utilitarian exchange in shooting galleries (Des Jarlais et al., 1986). These cultural practices, though deemed non-pathological by the researchers, are practices that are widely stigmatized (Stoller, 1998). Further, by showing the culture of people who inject drugs as generative of risk, external social and economic factors that shape risky behaviour were elided (Clatts, 1994; Glick Schiller et al., 1994). The act of describing these cultural traits functioned as a way to further delineate this group, and thus allow for more relevant governing. In fact, simply focusing on injection drug using culture and lifestyle opened a surface upon which interventions could spread.

Behaviour Change and Self-Advocacy (1987-1988)

The literature that followed in 1987 and 1988 focused more precisely on behaviour change initiated by both public health workers and by people who inject drugs (e.g., Becker &

⁴ The term “bridge” was used in the article published by Des Jarlais et al. (1985). Furthermore, AIDS was the infection of interest rather than HIV, because it is likely that at the time Des Jarlais et al. (1985) composed their manuscript the discovery of HIV had not been officially announced.

Joseph, 1988; Des Jarlais & Friedman, 1988; Friedman et al., 1987). People who inject drugs were now thought to be fully malleable, and thus were subjected to behavioural interventions aimed at preventing the transmission of HIV. In one proposed behavioural change framework, an aim was to attach new cognitive and emotional meanings to sharing needles (Des Jarlais & Friedman, 1988), thus behaviour change went below the surface of the body to modify people's thoughts and emotions. Behavioural interventions were also becoming more widespread as the federal government provided wide scale funding to support a research endeavour, the National AIDS Demonstration Research project, which assigned drug-injecting research participants to risk reduction interventions. The findings of this research were mixed, with some support for the enhanced risk reduction intervention (Page & Singer, 2010).

Around this time, people who inject drugs were beginning to advocate for themselves and push to legalize syringe exchange. There was a shift in popular discourse that revealed support for the efforts of people who use drugs to protect themselves from infection (Stoller, 1998). Though public health researchers had supported and in some instances worked to initiate these efforts (e.g., Friedman et al., 1987), people who inject drugs were now fashioning themselves as self-advocating and self-governing subjects. Linking their efforts to civic responsibility, these activist injectors exemplify a neoliberal cultural rationality that connects personal goals to the public good (Petersen, 1997). By supporting and collaborating with current and former drug users, researchers realized they could spur self-governance among this group. The loosening in some localities of restrictions on syringe possession meant that injectors were offered more autonomy, though this was buttressed with expectations of self-regulation. Through the interplay of research activities and grassroots actions, the image of the person who injects drugs as an activist began to form.

In 1988, the first legal syringe exchange programs (SEPs) in the United States began to open (Lane et al., 1993). These exchanges were formed and organized through the voluntary efforts of people who currently and formerly injected drugs, activists, researchers, and other advocates. In representations of the figure of the "injection drug user" in research publications, as well as in reports and news coverage of the newly opened syringe exchanges, the emerging discourse of the "injection drug user" as an active participant in self-care and advocacy appeared (Stoller, 1998). Early advocates and practitioners of needle exchange cited an ethics of pragmatism and social justice. For them needle exchange signified a protest against the exclusion and abandonment of people who use drugs (McLean, 2011). People who inject drugs were forming legally sanctioned organizations to protect themselves. In this mode of activity, they were not docile bodies being molded through outside disciplinary forces, but rather a group organized around social justice for drug users that sought to install the means for their own behavioural change.

Harm Reduction

The first stirrings of harm reduction in the United States occurred alongside the emergence of the "intravenous drug abuser" in public health research literature. John Stuenkel Parker began the first, albeit illegal, syringe exchange in the United States in 1983 in New Haven, Connecticut (McLean, 2013). However, harm reduction's roots can be traced to the

1970s formation of the *Junkiebond*, or Junkie League, of Rotterdam, which functioned as a type of trade union with a broad orientation toward drug user rights (Marlatt, 1996). Though input from the *Junkiebond* stimulated the Dutch movement toward a “pragmatic” and “humane” approach to stemming the AIDS epidemic among injectors, the initial goals of the *Junkiebond* were much broader (Marlatt, 1996, p. 784). The focus was on the “general situation of the addict,” which translated to work that involved consultations with government officials over such things as the distribution of methadone, police policy, and housing problems (Marlatt, 1996, p. 784; citing Wijngaart, 1991). This set of concerns, as well as the mission of the *Junkiebond*, are instructive for understanding the roots of harm reduction and how the movement differs in its purpose in the United States. The initial approach of the *Junkiebond* was political and service oriented, interested in drug user rights and basic needs.

The term “harm reduction” was subsequently coined in Liverpool, Merseyside, England in the early 1980s as health officials responded to a moral panic over heroin use and HIV/AIDS. In this setting and as applied by health authorities, harm reduction became more institutionalized and public health-oriented. McLean (2013) explains: “Where the Rotterdam union framed its mandate in terms of users’ rights, Merseyside health officials emphasized the public health and public order benefits of harm reduction...” (p. 22). Positioning harm reduction securely under the auspices of public health authorities has shaped its practices and politics ever since, and further cemented a disconnection from the movement’s anarchist roots (Smith, 2012; Stoller, 1998). The institutionalization of particular components of the harm reduction approach, mainly those having to do with interventions into the techniques of drug injection, steered the movement away from its earlier mission of mutual aid and an expansive approach to bettering the general situation of the drug user.

In New York, the powerful presence of the AIDS Coalition To Unleash Power (ACT-UP) aided drug user activists in their attempts to establish legitimate syringe exchanges through public and controversial direct action techniques (Lune, 2007). This connection to ACT-UP is perhaps partially responsible for the harm reduction movement’s emphasis on HIV/AIDS prevention to the detriment of the earlier mission to improve the general circumstances of drug users. As Heller and Paone (2011) note, “... ‘winning’ arguments for the expansion of syringe access have been rooted in the crisis of HIV/AIDS, rather than the need for a continuum of care and treatment services addressing problems of drug use” (p. 140). Preventing the spread of HIV was and continues to be the catalyzing force behind harm reduction activities in the United States, which limits the possibilities for this movement to address other causes of ill health among drug users, such as structured inequalities. In part, SEP administrators hesitate to pursue more progressive approaches to improving the general situation of the drug user because syringe exchange is politically unfavourable and administrators fear losing the minimal resources they do have, if they were to push the envelope (Lune, 2007).

The continued framing of harm reduction as a public health approach has disconnected it from its more radical roots. Smith (2012) writes “...the resultant disconnect between contemporary public health policy and the oppositional roots of harm reduction practice has sanitized the latter, actively drawing attention away from the role of structural factors underpinning the phenomena of drug dependence” (p. 209-210). Describing the founding philosophy of harm reduction as reflecting anarchist values and practice, Smith (2012) states, “... harm reduction discourse might therefore be seen as a disguised language developed to describe an emergent anarchist model of care for capitalism’s most oppressed, yet

symptomatic victims” (p. 213). Smith’s (2012) commentary and analysis of the current state of harm reduction in North America exhorts us to look back to the roots of harm reduction for guidance in re-shaping the movement into one that addresses the holistic concerns of drug users and the structural roots of their oppression.

Through its efforts to improve and recast the health of drug users, harm reduction is a manifestation of governmentality that regulates and normalizes bodies and creates subjectivities by implicating people who inject drugs in technologies of the self. Through harm reduction health promotion campaigns, people who inject drugs are instructed to take care of themselves by following sterile techniques of injection and in so doing an ethical subjectivity is produced (Fraser, 2004). In many ways, those labouring under the banner of harm reduction, researchers and activists alike, helped to produce the “injection drug user” subject who enacts an ethical identity in relation to peers and community through self-governance.

The governance of drug users through harm reduction policies and practices works in part through a reformulation of the discourse around drug use. Drug use is recast as a normal activity, but with a preferred range of behaviours and actions (O’Malley, 1999). Through this normalization, illicit drug users are enjoined to self-govern so that their drug using practices fall within the range of acceptability. In this way, the will of each individual drug user is aligned to the project of harm reduction (McLean, 2011; O’Malley, 1999). Much of the knowledge produced through harm reduction research efforts relies on risk calculations, which entice drug users to accept harm reduction educational interventions through their appeal to truth by way of probabilistic statistics (O’Malley, 1999). This production of statistics betrays an interest in population-level governance that surveils and normalizes such things as health and vitality. Thus, harm reduction as a mode of governmentality works to regularize bodies at both the individual and population level through a collection of statistics, which inform educational practices that inculcate people who inject drugs in a regime of self-care. Both the history of public health research publications and that of the formation of harm reduction show how the figure of the person who injects was produced through an intimate link to risk for infectious disease. This link will be explored in the next section through an analysis of qualitative interviews conducted with a sample of people who inject drugs in New York City.

METHODS

Qualitative in-depth interviews were conducted by the author with 40 economically marginalized⁵ people who inject drugs in New York City from February 2012 to May 2013. Interviewees were recruited through the use of a flier hung at two harm reduction centres and one public health research field office, all in Manhattan. With the exception of two interviews at a donut shop, the interviews took place in private rooms at the harm reduction centres and at the research study field site. In the interviews questions were asked to elucidate how the interviewees felt about their health. Much of the findings presented here were taken from a

⁵ Only participants who earn less than \$1,009.50 per month—a poverty threshold level set by New York City government—were interviewed for this research. Prior to participating in an interview potential interviewees were asked to confidentially report their estimated monthly income.

question that asked interviewees to identify their primary health concerns. The following questions were also asked during the interviews: How do you feel today? Do you feel healthy today? Can you describe a time in your life when you felt healthy? A time when you were unhealthy? What are some things you can do to make yourself feel healthy? The interviews lasted about 45 minutes each and the interviewees were compensated \$20 for their time and for their contribution to social science research. About a third of the interviews were transcribed verbatim by the author and the rest were transcribed by a professional transcription service. Data analysis was guided by an interest to understand the meaning of health for respondents and thus, the theoretical stance of the data analysis was grounded in phenomenology. The author read through the interviews multiple times and coded them according to emergent themes. This research was approved by the Institutional Review Board of Syracuse University.

In terms of race and ethnicity, age, and gender, the sample of individuals that were interviewed reflect the demographics of people who inject in New York City as collected by the city's department of health (New York City Department of Health, 2010). The age ranged in the sample from 21 to 59. Thirty of the interviewees identified as male and ten identified as female. When asked to identify race or ethnicity, 18 identified as white, 14 identified as Latino, 5 identified as African-American, 1 identified as Muslim, and 1 refused to identify a race or ethnicity.

RESULTS

In this section narratives of risk, which were inflected with harm reduction discourse, and narratives of illness, which focused on chronic health concerns, will be presented. It is important to recognize that harm reduction may have shaped the ways *some* drug users talk about their health and their selves though these instances were limited in scope and number. Narratives of illness heard during the interviews revealed the non-drug use related health concerns of low-income people who inject drugs and offered a way to understand the link between health and structural inequalities. These are representative of the majority of health concerns heard from the participants interviewed. They present health concerns that fell outside of the parameters of health put in place through public health and harm reduction governmentality.

Narratives of Risk

In limited ways the discourse disseminated by harm reduction is visible within interviewees' understandings of their health and ultimately their selves. In this section, all references to "harm reduction" are to its existence as a public health intervention rather than its historical configuration as a broader social justice movement. The behavioural practices advocated by harm reduction allow drug users to reduce the riskiness of their drug use, and thus promote a healthier way to use drugs. This claim toward healthiness has reshaped the conceptual contours of bodily health in some limited ways for the targets of these interventions—people who inject drugs. Since all but two of the interviews were conducted in

settings where harm reduction was promoted, it is perhaps unsurprising that this type of discourse emerged in the interviews. At the harm reduction centres, as well as at the research field site where interviews were conducted, participants received structured and unstructured education on harm reduction matters through interactions with staff and available educational literature.

Infectious disease and overdose were mentioned as health concerns for several interviewees, above and beyond other health problems, reflecting two of the main goals of harm reduction—to reduce the spread of blood-borne pathogens like HIV and hepatitis C and to prevent opiate overdose. For example, the immediate response of Dorian, a 40-year-old white bike messenger, to a question about his main health concerns reveals the mental proximity of harm reduction discourse. Dorian answered this inquiry right away with a concern about risk, although he may not have completely understood the question.

Kelly: These days what are your main health concerns?

Dorian: These days my health concern is not to contract HIV. I have... say that again?

Kelly: (repeats the question)

Dorian: I had hepatitis C since I have been 18 years old. I've been diagnosed with it. I am an exposure victim, not a carrier.

Dorian defined his health concerns through and with two of the key drug user health problems addressed by harm reduction interventions—HIV and hepatitis C.

Another focus of harm reduction interventions among drug users is the prevention of overdose. While overdose was mentioned by several people during their interviews, only one, Ashley, a 22-year-old biracial woman who is homeless, mentioned it as her primary health concern. When asked what her health concerns are, she responded:

Just like dying. Overdosing. Everybody I know is dying—three people in the last month. They just can't get right out of some place after a year and go back to doing a whole bundle. People go to sleep and they don't wake up. I'm just scared. I don't really sleep. I'm scared.

When Ashley referred to people getting out of “some place,” she meant a drug treatment program. This is a dangerous time for people who frequently use opiates because they have been abstinent for days or months causing their tolerance for opiates to decrease.

The interview with Dwight, a 53-year-old African-American man, was one of two interviews that took place in a setting unrelated to harm reduction—a donut shop. When he was asked questions pertaining to health, he proclaimed his HIV status. The exchange went like this:

Kelly: Okay let's talk about your health. This is a study about health so how do you feel these days? How's your health?

Dwight: It's fair. I have no AIDS. No AIDS.

Kelly: No HIV or?

Dwight: No HIV. Let me show you something. [retrieves a folded document from his wallet] I took an AIDS test over here... No hepatitis, no anything.

Kelly: That's great.

Dwight: Male, African male... I took it ten, twelve, two thousand eleven and it's been dated by these people. Okay, non-reactive and anything else non-reactive.

Dwight revealed his HIV negative status and produced documentation to, perhaps, prove that he was actually HIV negative. For him in the context of this interview, his health was intimately tied to HIV.

Across these three interviewees—Dorian, Ashley, and Dwight—infectious disease and overdose are prime concerns rising above other ailments they were concerned about or experiencing. Harm reduction educational interventions and practices address the foremost health concerns they mentioned in their interviews. Deciphering whether these risk narratives are the power-effects of governmentality may be a useless pursuit. However, when placed next to research, which has convincingly shown that these types of narratives can be linked to the governing practices and discourses of harm reduction (Bourgois & Schonberg, 2009; Campbell & Shaw, 2008; Fraser, 2004), it becomes a possibility that Dorian, Ashley, and Dwight are speaking the discourse expected from drug-injecting subjects.

Narratives of Illness

Most of the health concerns expressed by interviewees were not articulated in terms of risk but rather had to do with chronic illnesses. While telling the stories of their illnesses, interviewees did not often make mention of their drug use, and the chronic conditions they dealt with did not appear linked to drug use. Through telling these stories, the interviewees showed the efforts they made to address their conditions or in some instances expressed worry over their inability to address their conditions.

In terms of evidence-based, risk-reduction techniques, harm reduction has shown much success as a public health intervention in stemming the spread of HIV, but if these interviews are any example, health is still poor among low-income drug injectors. Besides health problems, many of the interviewees also experienced housing instability, which in some instances created or worsened health problems. This section will examine two illness narratives that vividly reveal the link between poverty and health. Offering these illness narratives and making clear their intersection with socially structured disadvantage reveals that individual-level interventions may be inadequate to address the health concerns of socially marginal populations.

Dan, a 22-year-old white man, presented an account of homelessness together with a narrative of illness that reveals the negative health impacts of poverty and how the health care system in the United States can exacerbate illness. In explaining how he came to reside in New York City—he is originally from Long Island—Dan also described how he became homeless:

Well, I was living with my girlfriend, and I had three jobs. I had custody of my brother. She had a kid too, and we ended up breaking up, and everything was in her name. So I was living out of my truck for a little while. I was working. I was doing fine. I was taking care of my brother. Somebody stole my truck. Yeah, so I lost all my jobs and just became homeless, and it was just pretty much downhill from there. Yeah, I lost custody of my brother. I mean my aunt has him. He's okay, but I just kind of ended up out here [in New York City]. It's actually a lot easier to hustle out here. It's a lot easier to be homeless out here than it is on Long Island.

At the time of this interview Dan had been living in a shelter in Brooklyn for about a month. Prior to that, he was living on the street.

It is important to point out that the harm reduction centre where this interview took place played something of a role in Dan's life. He explained:

I thought it was a place for homeless people because everybody that I knew came here, and I'm like, 'Oh, why is everybody coming here?' And I started volunteering, and I've used needles, so it worked out... It's like a hangout.

The syringe exchange services of this harm reduction centre occupy a minor position in Dan's characterization of his introduction to this so-called hang-out. It "worked out" for him to become a participant and volunteer because he injects drugs. However, Dan didn't identify the harm reduction centre as a place that addresses his injection drug use but rather, as a place for homeless people like him to hang out. Dan's prioritized needs have more to do with his homelessness than his injection drug use. However, it is his injection drug use that allowed him to gain entrance to the harm reduction centre, which he describes using for purposes of hanging out with his social network and to pass time volunteering.

When asked what his main health concerns were, Dan said: "My main health concerns? Pretty much just my diabetes." During the interview, it was clear that diabetes shaped Dan's life, as well as how he understood his health. He had previously found employment in the food service industry and described this work environment as helpful for addressing his diabetes. Notably, he did not mention the health risks associated with injection drug use though going through his drug use history revealed weekly injection of heroin, as well as the use of crack and prescription painkillers. When asked how he managed his diabetes while living on the street a story of desperation and frustration with Medicaid sanctions and hospital bureaucratic rules emerged. He described it:

Well, it was difficult in the beginning because I didn't have as much hustles and able to make as much money. So I wasn't doing so good in the beginning, and my Medicaid got cut off because I accidentally set up a case out here [in NYC] while I had a case in Long Island. They cut it off for six months. I almost died like four or five times. I was in the hospital every week because I didn't have my insulin. I can't go three days without my Lantus.⁶ I take two different types, and I can't. I just – I get sick beyond all means. I got no energy because what the insulin does is it literally makes energy in your body, so if you don't have insulin, you don't have energy. So I couldn't even make money if I tried. I was a wreck.

Kelly: Because you didn't have Medicaid, they wouldn't give you insulin?

Dan: So I would have to go into the hospital in DKA, diabetic ketoacidosis. That's when my sugar goes completely too high. I black out. I can just die, and that's pretty much the only way they would take me is if I was in DKA. And I'd have to do three days, and I'd be out for four days, three days.

Poverty, Medicaid sanctions, and hospital policy worked against Dan in acquiring the medication he needed to treat his diabetes. To receive his medication, Dan was compelled to push his diabetes to acute levels and seek treatment in the emergency room where he was not allowed to take medication with him. Faced with this dire situation, Dan's primary focus is placed on his diabetes though he did show some minor concern for contracting HIV. When asked his usual reasons for visiting the doctor, which he does about two times a month now that he has health insurance, he replied: "My sugar." Then, he continued: "To make sure everything is in check, to make sure my A1C's⁷ good. Just general... I take HIV tests like every three months, other tests..." Though Dan was concerned about contracting HIV and has

⁶ Lantus is a long-acting insulin that is taken once a day as a form of diabetes treatment. It comes in the form of a pen that uses a small, thin needle to inject the medication.

⁷ The A1C test measures average blood glucose control for the past two to three months.

himself tested while at the doctor, his diabetes is the motivating force for making the doctor's visit. Visiting the doctor for his diabetes offers access to HIV testing rather than the other way around.

John, a 56-year-old Puerto Rican man, presented a narrative of illness that also links health to poverty and housing instability. Though residing in transitional housing at the time of the interview, John was homeless and living on the street the year prior. After losing his job of 12 years in the maintenance department of an apartment complex, John began living on the streets. He attributed the year he lived on the streets directly to the loss of his job. Now that he is off the streets and working part-time as a peer educator at the harm reduction centre where the interview took place, he's been able to focus on his health. When asked what his main health concerns are these days, he replied: "My health is my main concern right now. I do have health issues... You know, I was homeless. I didn't have no insurance. I had nothing." John listed his health concerns as "an aneurysm, kidney stones, COPD [chronic obstructive pulmonary disease], and asthma and hypertension." At various points while discussing his health, John showed concern for the effects of being homeless and having no insurance on the health conditions he knew he had. He explained:

I had hypertension for a very long time. That I knew. So you know when I was homeless I knew that I had hypertension. The thing was that all the time I was walking around I didn't have insurance. I used to say, 'How am I going to get medication' and I knew my blood pressure was high because I could feel it.

Eventually, John was able to see a doctor through a homeless outreach program run by a local hospital, and he expressed deep gratitude for this connection to health care. As John explained, he is now dealing with the health consequences of a couple of years spent without insurance and therefore, without medication. John said:

... all the time I knew that I had high blood pressure but I had no way to take care of it and the fact that now, you know, when I found Dr. Marquez and I'm getting meds now it's almost like, you know, I'm getting the meds but because of the waiting time of going a couple of years without meds caused the aneurysm to happen. You know, so then I used to worry about it a lot. 'Oh my god, what am I going to do? I can't get meds. I can't do this.' I didn't know that I had the aneurysm. All I knew was I had high blood pressure. I didn't know I had COPD and I knew I had a slight case of asthma because everybody used to tell me, 'you breathe really heavy,' but now I don't, I don't feel like... I mean, I know I'm not real healthy. Like I said the things that I need to be taking care of right now are being taken in. I'm seeing the doctor that I need to see.

John's injection drug use did not figure into his explanation of his health. It seems that he has other overwhelming concerns. John was hit particularly hard by his loss of employment, which left him living on the streets. Unable to plug in to any social safety nets, John's health conditions worsened and he was left permanently affected by ailments that could have been ameliorated if he had access to health care and stable housing.

Through discussions of health with economically marginalized people who inject drugs, it was clear that despite their status as risky subjects, these individuals did not often prioritize the concerns focused upon by harm reduction interventions—HIV/AIDS, hepatitis C, and overdose. Rather, people talked about common chronic ailments such as diabetes, asthma, and hypertension. The structural roots of the circumstances that led to their illnesses are related to inequality, and the inadequacies of the social welfare and health care systems in the U.S. Often conditions of poverty and homelessness made access to health care services and specifically attaining health care insurance difficult if not impossible.

LIMITATIONS

Several omissions with regard to methodology and reporting of data affect the findings presented here. That none of the interviewees identified as indigenous or transgender means that the overall picture of health presented in the results is incomplete. Furthermore, no illness narratives from women were included in the results section. However, their accounts of health and illness figured into the conclusions made below and throughout the chapter. Finally, no community members were consulted during the analysis of data or the formation of conclusions. This limitation breaks with the harm reduction ethos, which insists on the prominence of community member voices and concerns. Informal consultation did occur when these findings were presented at the 10th National Harm Reduction Conference in October 2014. The presentation was not met with critique, though it is possible that criticism was withheld. Rather, it ignited a hearty conversation about the difficulties people who use drugs face when seeking health care.

CONCLUSION

The drug-injecting subject was created in the early 1980s as part of a risk-group organizational schematic that placed the onus for HIV infection on the individual person, rather than placing it on behavioural practices or simply, the virus itself. Though early investigators of AIDS among gay men shifted from a lifestyle model of analysis to a model that focused on the virus (Oppenheimer, 1988), among people who inject there remained a focus on lifestyle as evidenced by the ethnographic study of the culture of injection (e.g., Des Jarlais et al., 1986; Friedman et al., 1986). Research in the mid-1980s that described the cultural traits of communities of people who inject drugs served to refine and differentiate the figure of the injection drug user. Through behavioural interventions and educational campaigns people who inject drugs were governed as a population and as individuals instilled with the will to take care of themselves.

By interviewing these subjects of risk it became clear that concerns over chronic conditions that led to acute episodes of ill-health were of greater importance. The interviewees did not often prioritize the illness that formed their epidemiologic identity—HIV—nor did they often discuss the concerns that form the foci of harm reduction interventions—HIV, hepatitis C, and overdose. Since the forty individuals interviewed were all actively injecting drugs, they could fall under the care of the harm reduction movement and most of them did, though this movement mainly addresses health in terms of its relation to unsafe drug use practices. Presently, the narrow public health mandate of harm reduction externalizes non-drug-use-related health issues to other service providers, and to the individual drug user. This means that individuals living in positions of extreme vulnerability must self-manage.

Looking back upon the roots of the harm reduction movement to the *Junkiebond*, reveals that a broader sensibility with regard to the concerns of drug users is possible. This is not to say that harm reduction in the mode of health promotion should expand its intervention into the lives of drug users, intervening in new places and on new levels of intensity. Rather, harm reduction as a social movement must focus on a more structural level to reduce the harms

experienced by low-income people who inject drugs. The harm reduction movement can expand its mission through an inclusive re-formulation of what is meant by harm. This could translate into support for self-directed efforts among people who inject drugs to define their primary health concerns, and to the provision of resources to address them. By addressing the self-described health concerns of people who inject drugs, harm reduction could subvert the types of governing power that regulate populations in relation to a singular concern (e.g., infectious disease) and instill practices of self-care (due to a lack of available resources).

The findings of this chapter point to the need for a movement that is supportive of care, broadly construed and easily accessible, to those most negatively affected by inequalities and the neoliberal emphasis on personal blame, rather than narrowly-focused movements that parcel out only certain types of care. Social marginalization manifested through poverty, homelessness or housing instability, and the stigmatization of drug use detaches people from necessary resources and support, exacerbating health problems, as evidenced by the experiences of Dan and John. The harm reduction movement should expand its mission by working to combat social policies and informal social practices that make people who use drugs especially vulnerable to impoverishment and disconnection from community networks of care.

Chapter 502

HARM REDUCTION HIPSTERS: SOCIO-SPATIAL-POLITICAL DISPLACEMENT AND THE GENTRIFICATION OF PUBLIC HEALTH

Christopher B. R. Smith*, PhD

School of Social Work, Memorial University, St. John's, Newfoundland, Canada

ABSTRACT

Background: The hipster has re-emerged as the reigning subcultural identity of the early twenty-first century, spawning an emergent body of critical commentary. Tracing the relationship between hipsters, the philosophy and practice of harm reduction, and the depoliticization of institutional public health policy, this paper critically interrogates 'harm reduction hipsters' and how members of this increasingly ubiquitous global subculture are actively implicated in various forms of social, spatial, and political displacement, resulting in the consequent 'gentrification of public health.' **Methods:** Drawing from the author's cumulative ethnographic experience, this article employs critical theories concerning subcultures and social movements, radical direct action politics, and contemporary patterns of gentrification and urban redevelopment/ 'revitalization,' thus contributing to central debates in critical drug studies regarding the role and importance of equitably incorporating active drug users and/or people with lived experience of substance use in harm reduction programs and interventions through relationships based on the notion of 'collaborative autonomy.' **Results:** Arguing that the contemporary subcultural figure of the hipster is actively implicated in three interrelated forms of social, spatial, and political displacement, the paper concludes by excavating the inherently political origins of harm reduction philosophy and practice and asserting the fundamental importance of resituating people who use drugs as the central driving force behind the movement.

Keywords: harm reduction, hipster, subculture, service user involvement, pathology paradigm, drug user organizations, gentrification, public health

INTRODUCTION: THE HIPSTER-IZATION OF HARM REDUCTION

Attempting to accommodate active injection drug users (IDU), the conference organizers established a ‘safe room’ equipped with a stockpile of injection supplies and a considerable amount of the narcotic antagonist naloxone. Given my sociological curiosity regarding in/formal drug consumption sites, I visited the safe room repeatedly throughout the three-day event, and during each visit the space was almost completely devoid of users, its only inhabitants volunteer staff and a rotating cast of what I then termed ‘harm reduction hipsters:’ mostly young, educated, white, middle class, ex-suburbanite kids with relative socio-economic privilege who worked in various harm reduction capacities and dressed in accordance with normative late-capitalist hipster style: skinny jeans, plaid shirts, black horn-rimmed glasses, thrift shop t-shirts bearing working class signifiers, and among men, ironic facial hair (i.e., handle-bar moustaches etc.).¹ Further demonstrative of this odd imbalance², by any measurement there was orders of magnitude more naloxone present during the conference than any form of opiates, illicit or otherwise. Each time I visited the ‘safe room’, in other words, instead of active injection drug users I was greeted by a group of leather-jacket clad, tattooed hipsters sitting around trading gossip and ‘war stories’ from the ‘front lines’ of harm reduction outreach (excerpted from the author’s field notes from an unnamed American harm reduction conference, Fall 2010).

Contemporaneous to the widespread adoption of harm reduction as institutionalized public health policy throughout the later 20th and early 21st centuries, a new—or, rather, old—subculture (re-)emerged to become a ubiquitous global fixture: the “hipster.” Given that the rebirth of hipster (sub) culture so closely coincided with the rise of harm reduction as institutionalized public health policy, it is perhaps unsurprising that hipsters have assumed a prominent position within the harm reduction movement in recent years, becoming leading proponents of institutionalized public health policy and practice. In the arguments that follow, however, this chapter asserts that hipsters have not served to strengthen or enhance the political trajectory of the harm reduction movement. Instead, by illustrating the various forms of social, spatial, and political displacement in which they are implicated, the chapter works to suggest that ‘harm reduction hipsters’ are actively complicit in what this paper terms the ‘gentrification of public health,’ a concept that is explicated in detail in later sections of the chapter.

The primary argument of this chapter, therefore, is that the “hipster-ization” of harm reduction has been directly responsible for three closely related and intersecting forms of social, spatial, and political displacement, thus directly leading to the corresponding gentrification of public health. Moreover, these three inter-related displacements un/consciously function to privilege and empower the prevailing pathology paradigm or biomedical ‘brain disease’ model of addiction research and treatment, a paradigm that is inseparable from the apolitical agenda of institutionalized public health policy and the depoliticization of harm reduction practice more generally (Hathaway, 2001; Keane, 2003; Miller, 2001; Reinerman, 2005; Roe, 2005; Smith, 2012b). As this paper asserts, hipsters are

¹ For more on contemporary hipster style, see: Greif (2010a), Haddow (2008), and Lanham (2002).

² Anticipating a low number of drug/service users or ‘peers’ in attendance at the conference, I wrote a provocative refrain into my talk, repeated in different iterations on at least three separate occasions: “how many institutional harm reduction agencies funded a service user or ‘peer’ to attend this conference?”

therefore complicit in the institutional co-optation and recuperation of harm reduction³, in the form of politically sanitized, ‘disease model’-driven public health policy.

Beginning with a background discussion concerning the emergence of contemporary hipster subculture, the chapter details the radical political origins of harm reduction practice in tandem with the depoliticization of institutionalized public health policy.

After tracing the origin and development of contemporary hipsterdom and its relationship to institutionalized harm reduction practice, the chapter then turns to address the complicity of harm reduction hipsters in social, spatial, and political forms of displacement within the harm reduction movement, before turning to a concluding critique of the ‘mainstreaming’ of harm reduction and the *political imperative*⁴ of situating people who use drugs (PUD) as the central driving force behind the movement.

METHODOLOGY: ETHNOGRAPHIC APPROACHES TO ADDICTION, CONTEMPORARY HIPSTERDOM, AND THE DEPOLITICIZATION OF INSTITUTIONALIZED PUBLIC HEALTH POLICY

In order to place hipster subculture in historical and contemporary context, it is first necessary to situate my own research positioning and identity as a politically engaged academic, activist, and advocate for people who use illicit drugs. Providing background to the emergence of what might be termed ‘second wave’ hipsterdom in the 1990s, this section therefore seeks to self-reflexively identify my personal research positioning vis-à-vis harm reduction and hipster subculture, as well as detail the theoretical framework underpinning the social, spatial, and political displacements that form the central argumentative structure of this work. Prior to interrogating the emergence of contemporary hipsterdom, however, it is important to briefly discuss the ‘place’ of qualitative—particularly ethnographic—methods in what Keane (2009) termed ‘critical drug studies.’

The vast majority of traditional research regarding drug use/users, and ‘addiction’ is overwhelmingly characterized by quantitative, epidemiologically-focused approaches absent of social considerations (Bourgois, 2002; Martin & Stenner, 2004), where the predominance of quantitative methods is evidenced in “funding priorities, research turf battles and hierarchical publication prestige” (Ciccarone, 2003, p. 115). The field of addiction research has thus been staked out as the primary disciplinary domain of quantitative public health scientists, where, as Bourgois (2002, p. 260) succinctly suggests, “epidemiologists are still convinced that it is possible to obtain accurate numbers that are useful for solving urgent social problems.” Recent debates in the field of addiction research have suggested the need for increased ‘cross-methodological’ dialogue and debate (Bourgois, 2002), proposing qualitative research as “either the ‘antidote’ or the necessary complement” to quantitative

³ A term coined by the mid-20th Century European avant-garde movement the *Situationist International*, Sadie Plant (1992, p. 75) defines the *recuperation* of dissenting forces as a term “intended to convey the subtlety and effectiveness by which criticism of the spectacle is enlisted in its support.”

⁴ By consciously framing user-driven forms of harm reduction as a *political imperative*, I am both borrowing from and critically flagging the central, privileged focus on public health—and consequent deprioritization of human rights—in the Canadian HIV/AIDS Legal Networks’s (2005) “*Nothing About Us Without Us*”- *Greater, Meaningful Involvement of People Who Use Illegal Drugs: A Public Health, Ethical, and Human Rights Imperative*.

methods (Martin & Stenner, 2004, p. 395). Demonstrating this acute imbalance, several recent issues of prominent addiction journals have been devoted to qualitative—and particularly ethnographic—methods in drug research⁵. The overt focus on ethnography in these publications (Bourgois, 2002; Maher, 2002; Moore, 2002; Power, 2002; Sifaneck & Neaigus, 2001), as Ciccarone (2003, p. 116) notes, “illustrate how epidemiology and ethnography are differently valued within the bio-medical establishment,” where the “hegemony of ‘publish or perish’” serves to privilege “reductionist science over time intensive field research.”

Composed of a series of ethnographic vignettes drawn from cumulative participant-observation fieldwork at harm reduction and addiction treatment sites in Canada (namely Toronto) and the US (namely New York and Philadelphia), observations were collected throughout the author’s doctoral and postdoctoral research, where ethical approval was granted by York University (Toronto, Canada) and the University of Pennsylvania (Philadelphia, US) respectively. In discussing the limitations of “traditional epidemiological methods for explaining patterns of infections among hidden populations engaged in illegal or taboo activities,” Bourgois and Bruneau (2000, p. 328) insist that ethnographic participant-observation methods “urgently need to be integrated into substance abuse and HIV prevention studies if we are to understand fully the implications of the numbers we collect and, also, if we are to prevent complex statistical data from being misinterpreted and manipulated politically.” In this article and elsewhere, Bourgois (1998, 2002) employs ethnographic vignettes as a useful tool for critically illustrating the social and structural dimensions of addiction, harm reduction and treatment policy. Following Bourgois, the self-reflexive ethnographic vignettes that serve to structure this investigation can be seen as a counter-balance or complement to the quantitative, epidemiologically-focused orientation of traditional ‘addiction research’, providing a grounded, politically informed, and socially engaged analysis of contemporary trends within the harm reduction movement in North America, as well as the broader global context of the movement. Prior to introducing the ethnographic elements of this work, however, it is necessary to provide further context concerning the origin and development of hipster subculture and its relationship to the explicitly political origins of harm reduction theory and practice, as well as its depoliticized manifestation in the form of present day institutional public health policy (Smith, 2012b).

Contemporary hipsterdom emerged around the turn of the twenty-first century, undergoing a succession of subtle social and aesthetic permutations over the last decade (Greif, 2010c). In critically considering its present day manifestation, however, it is important to bear in mind that the first use of the term hipster corresponded with new styles of jazz music in the US during the 1950s “Beat”-era (Mailer, 1957).

The American off-spring of French existentialism, mid-twentieth century hipsters borrowed heavily from the aesthetic, vernacular, and musical culture of African Americans, seeking to “exist without roots,” and “journey into the rebellious imperatives of the self,” thus creating a subculture of “urban adventurers who drifted out at night looking for action with a black man’s code to fit their facts” in neighbourhoods such as New York’s Greenwich Village (Mailer, 1957, p. 3-4).

As opposed to the original 50s-era hipster, however, over and above a series of depoliticized, pastiche aesthetic signifiers (Greif 2010a, 2010c, 2010d; Haddow, 2008),

⁵ For example, see: Rhodes & Moore (2001), Moore & Maher (2002), and Moore & Rhodes (2004).

contemporary hipsterdom constitutes a ubiquitous post-globalization subculture inextricably implicated in broader social, political, and economic forces (Clayton, 2010). Borrowing from Lanham's (2002, p. 2-3) *11 Clues You Are a Hipster*, twenty-first century hipsterdom can be defined by its relationship to socio-economic privilege, the adoption of de-contextualized working class signifiers, and superficial political orientation. The first of Lanham's (2002, p. 2) clues suggests that many hipsters "graduated from [...] liberal arts school[s]." Second, Lanham asserts that contemporary hipsters "frequently use the term 'post-modern' (or its commonly used variation 'PoMo') as an adjective, noun, and verb." Perhaps most relevant to the analysis contained within this essay, featuring at number nine on the list of clues, Lanham (2002, p. 3) suggests that second wave hipsters "enjoy complaining about gentrification even though [they] are responsible for it" themselves. Albeit in some cases unconsciously, hipsters therefore constitute active agents of gentrification, a process intimately related to notions of class displacement (Glass, 1964). An additional defining characteristic of modern-day hipster subculture is, as many contemporary cultural critics have argued, a vehement rejection of any form of hipster self-identification. Here, as Greif (2010d) describes, "[n]o one, it seemed, thought of himself as a hipster, and when someone called you a hipster, the term was an insult. Paradoxically, those who used the insult were themselves often said to resemble hipsters." Resisting any form of hipster self-identification is, in other words, perhaps one of the most central tenets of the subculture (Greif, 2010a, 2010d; Haddow; 2008).

As Haddow (2008) argues, the contemporary hipster aesthetic is constituted from an appropriated mishmash of decontextualized—and thus *depoliticized*—working class and/or revolutionary cultural symbols⁶. Hipsterdom, in other words, is a global sub-cultural movement driven by an ostensible affinity with marginal, lower-class urban populations (including people who use drugs), based on the apolitical bricolage of implicitly political signifiers (Hebdige, 1979), utterly divorced and abstracted from their original meaning and context. As an "artificial appropriation of different styles from different eras," Haddow (2008) further asserts that it is "this ironic lack of authenticity that has allowed hipsterdom to grow into a global phenomenon," representing the "end product of all previous counter-cultures ... stripped of [...] subversion and originality;" as the following arguments suggests, this statement might equally apply to the contemporary state of harm reduction and its global infection by the pathology paradigm for addiction research and treatment (Courtwright, 2010; Reinerman, 2005).

In order to adequately contextualize the three forms of social, spatial, and political displacement that are perpetuated by harm reduction hipsters—all of which effectively culminate in the gentrification of public health—it is therefore also important to detail both (1) contemporary theories of gentrification, and (2) the radical political origins of harm reduction philosophy, theory, and practice. Closely corresponding to the global rise of the pathology paradigm following the AIDS epidemic, Smith (1996) argues that the 1980s witnessed a profound shift in the nature of gentrification. Characterized by "*revanchism*"—an ideology rooted in notions of revenge that is deeply inscribed by race and social class—Smith (1996, p. xviii) suggested this emergent pattern of gentrification constituted "a revengeful and reactionary viciousness against various populations accused of 'stealing' the city from the

⁶ Emblematic working-class symbols employed by second-wave North American hipsters include *Pabst Blue Ribbon* and *Labatt 50* beer in the US and Canada respectively (Greif, 2010a, 2010c). One need only think of t-shirts emblazoned with the image of Che Guevara to understand how revolutionary signifiers are recuperated and decontextualized by contemporary hipster subculture.

white upper classes.” The *revanchist city*, Smith (1996, p. 227) insisted, was thus a “divided city, where the victors [were] increasingly defensive of their privilege ... and increasingly vicious defending it.” Based in part on case studies of Vancouver, Smith (2002) and Smith and Derkson (2002, p. 64-67) more recently suggested that this increasingly vengeful pattern of gentrification has proliferated to become a “global urban strategy,” entailing a “generalization of gentrification in the urban landscape.”

Representing a “consummate expression of neo-liberal urbanism” (p. 88), Smith and Derkson (2002, p. 67) argue that “gentrification as global urban strategy” rests on five core characteristics, each of which directly maps on to what this chapter terms the *gentrification of public health*, namely: “the transformed role of the state, penetration by global finance, changing levels of political opposition, geographical dispersal, and the sectoral generalization of gentrification.”

Drawing from the work of contemporary gentrification theorists, I therefore understand the gentrification of public health as an expression of the global proliferation of the addiction-as-disease model and its ubiquitous stranglehold on international public health policy. Extending this framework, the gentrification of public health is therefore informed by both the increasing interdependency between nation-states and “footloose,” “hypermobile” global capital (Harvey, 1990; Lees, Slater, & Wyly, 2008; Sassen, 1998; Smith, 2002; Smith & Derkson, 2002), and increasingly organized, increasingly globalized emergent forms of user-driven direct action-based activism, organizing and opposition (VANDU, 2010). Having assumed a position of global dominance in public policy, the globalized gentrification of public health therefore maintains vested interests in perpetuating the disease model of addiction—what Granfield (2004) has aptly termed “*addiction fetishism*”—at the same time as oppositional factions, from radical academics to autonomous user groups, simultaneously develop new modes of resistance and critique (Alexander, 2000, 2008; Canadian Harm Reduction Network, 2008; Cheng & Smith, 2009; Granfield, 2004; Jurgens, 2008; Kerr, Douglas, Peeace, Pierce, & Wood, 2001; Kerr et al., 2006; Reinerman, 2005; Roe, 2005; Smith, 2012b; VANDU, 2004, 2010).

Demonstrating how the North American harm reduction movement began as a clandestine, grassroots social movement (Reinerman, 2005; Roe, 2005; Smith, 2011a; Stoller, 1998), Smith (2012b) has suggested that the founding theory, philosophy, and practice of harm reduction was therefore in/directly premised on anarchist principles of mutual aid, distrust of hierarchy, and anti-authoritarianism (Bey, 1985; Crimethinc, 2002; Day, 2004; Graeber, 2002).

Through tactical affinity-based alliances with similarly marginalized and stigmatized urban populations—namely the queer community, people living with HIV, and the radical direct action tactics of activist and advocacy groups such as the *AIDS Coalition to Unleash Power* (ACT-UP)—the dawn of the HIV/AIDS epidemic during the mid-1980s was widely seen as the catalyst for a diverse range of “underground,” grassroots harm reduction interventions across North America, which in turn eventually became adopted as depoliticized public health policy, marketed by the cost/benefit, “bottom line” analysis of harm reduction and explicitly framed by the disease model of addiction (Maskovsky, 2001; Reinerman, 2005; Roe, 2005; Stoller, 1998).

Attributable to the global adoption of the pathology paradigm, the institutionalization of harm reduction therefore directly resulted in the erasure or displacement of the movement’s explicitly radical, oppositional political origins, becoming obscured by the ostensibly

“objective”—yet fundamentally ideological—discourse of biomedicine and public health science, particularly epidemiology (Bourgois, 2002; Hathaway, 2001; Hwang, 2007; Keane, 2003; Miller, 2001; Reinerman, 2005; Smith, 2012b). Effectively functioning to divorce and abstract the notion of addiction from the underlying structural forces responsible for its production, the rise of the biomedical model soon led to a dramatic shift in harm reduction discourse away from critiques of the social forces that served to produce and perpetuate harm by resituating addiction as a function of the addicted subject’s innately faulty neuro-chemical circuitry (Alexander, 2000, 2008; Granfield, 2004; Mate, 2008; Roe, 2005; Smith, 2012b).

Throughout the following sections, this essay argues that harm reduction hipsters have been actively complicit in three interrelated forms of social, spatial, and political displacement, effectively resulting in the broader gentrification of public health. As this chapter subsequently suggests, however un/conscious or in/direct, irrespective of their varying degrees of involvement, the role of harm reduction hipsters in this process has been irrefutable. Owing to the fact that there exists little or no literature (scholarly or otherwise) concerning the demographic composition of the harm reduction workforce in any given local or national context, assumptions regarding social class contained in this analysis are, therefore, a significant limitation to the research.

Based on the author’s personal experience, as well as anecdotal research observations from colleagues in the fields of critical drug studies, public health, and harm reduction, however, the socio-economic characteristics of the harm reduction workforce—from medical staff (i.e. physicians, psychiatrists, psychologists, and street nurses, etc.), to administrators (i.e., Executive Directors, board members, grant writers, front desk personnel) to ‘front line’ workers (i.e., outreach workers, ‘client’ support workers, addiction counsellors)—exhibits considerable variation, depending on a host of different factors. Chief among such factors are sources of public and private funding, organizational structure, management, differences in regional and/or state/ provincial/territorial policy, models of local and national governance, the drug use patterns that serve to characterize a given city or region, the socio-spatial character of drug/service user communities⁷, and prevailing public and professional attitudes concerning harm reduction, (public) drug use, and addiction treatment models in any given socio-spatial-political context. As this chapter works to assert, however, in spite of the sometimes stark differences in its various regional manifestations, the phenomena of ‘harm reduction hipsterdom’ is indeed global in scope, and as the following sections describe, the global ‘gentrification of public health’ is already at an advanced stage. Even in the absence of peer-reviewed literature relevant to the demographic composition of the ‘front-line’ harm reduction workforce, however, the ethnographic vignettes that follow clearly demonstrate that the various forms and dimensions of displacement brought on and perpetuated by harm reduction hipsters have become glaringly apparent.

⁷ Circumnavigating the explicitly capitalist-inscribed terms “client” or “consumer” employed by public health authorities to describe the subjects of harm reduction or addiction treatment services, Smith (2012b, p. 211) posits the term *drug/service user* as having “a potentially productive, fluid interchangeability” by encompassing both active illicit drug users’ utilization of harm reduction services such as needles exchange programs (NEPs) and/or subjects of addiction treatment programs such as MMT.

DISPLACEMENT #1: SOCIAL CLASS, USER SPACE, AND HIPSTER GENTRIFICATION

Centred on the notion of gentrification, the paper now turns to interrogate the first *spatial* form of displacement perpetuated by harm reduction hipsters. As a satirical pop cultural point of departure, the entry for “gentrification” on the popular website-turned-book entitled *Stuff White People Like* (Lander, 2008) reads:

Perhaps the safest bet a white person can make is to buy a house in an up-and-coming neighborhood. White people like to live in these neighborhoods because they get credibility and respect from other white people for living in a more ‘authentic’ neighborhood where they are exposed to ‘true culture’ every day.

The largely white sub-cultural shades that together compose modern hipsterdom are often overtly associated with processes of gentrification (Clayton, 2010; Greif, 2010a). As “neighbourhood pioneers,” therefore, hipsters often inhabit—and moreover demarcate—what Neil Smith (1996, p. 190) termed the “redevelopment frontier,” a shifting, socio-spatially contested boundary or border delineating spaces of *disinvestment* from those of *reinvestment* in both urban planning and urban redevelopment discourse, as well as the wider public imagination. Before addressing the centrally important role of hipsters, however, it is useful to revisit Ruth Glass’s founding definition of what is today referred to as “classic gentrification” in urban studies scholarship concerning gentrification and urban redevelopment or “revitalization” initiatives (Lees et al., 2008):

One by one, many of the working class quarters of London have been invaded by the middle classes ... Shabby, modest mews and cottages [...] have been taken over, when their leases have expired, and have become elegant, expensive residences... Once this process of ‘gentrification’ starts in a district it goes on rapidly until all or most of the original working class occupiers are displaced and the social character of the district is changed (Glass, 1964, p. xvii-xix).

As Glass asserts, the notion of class displacement is thus of fundamental importance to the founding definition of gentrification. Invocations of hipsterdom, as Clayton (2010, p. 29) further argues, often represent a cipher for discussions of “gentrification and neighbourhood change,” where class displacement is understood as a central element in both historical and contemporary patterns of urban “regeneration” or “revitalization” (Glass, 1965; Lees et al., 2008; Slater, 2004; Smith, 1996). Not unlike the arts community that they are so commonly associated, aligned, and involved with, therefore, hipsters can thus be seen as representing a particular sub-type of gentrification “shock troops”⁸, a group that often boasts of its tolerance for (and, moreover, embrace of) ethnic, cultural, gender, and/or class-based forms of “difference” (Blackwell, 2006; Caulfield, 1989, 1994; Clayton, 2010; Slater, 2004). In much the same manner as hipster style is constituted from a bit-piece pastiche-like assemblage of decontextualized—and thereby *depoliticized*—marginal, lower/working/under-class signifiers, Greif (2010a, p. 10) argues that “the ‘white hipster’ fetishize[s] the violence, instinctiveness, and rebelliousness of lower-middle-class [neighbourhoods]” yet with “the

⁸ This statement is drawn from the old adage that “*artists are the shock troops of gentrification*.” A military-based metaphor, such invocations fit neatly with invocations of gentrification as a “battleground” or “war zone” (Smith, 2014).

ethnicities scrubbed off,” thus effectively serving to “recolonize[e] urban neighbourhoods with a new aesthetic.”

Gentrification is a process that is always already seduced by the “sketchy” or “dodgy” nature and character of disordered, post-industrial, immigrant working class urban landscapes (Smith, 2010, 2011). In this sense, Neil Smith’s (1996) notion of the *new urban frontier* represents a transitional space where hipsters and junkies, artists and winos, yuppie “DINKs” and sex trade workers intermingle, and—at least for a time—co-exist⁹. Starting with the social construction or invention of the addict as a typology of moral-criminological deviance at the dawn of the 20th century, throughout the course of our “narcotic modernity,” furthermore, such marginal urban areas have often been associated with the “disorder of drugs” (Brodie & Redfield, 2002; Derrida, 1993; Fraser & Moore, 2008; Smith, 2010, 2011, 2012a), becoming the space of brothels and “crack houses” or “shooting galleries”¹⁰, “alkie” dive bars and “junky” parks. From this vantage point, it is therefore perhaps unsurprising that our global cities’ most notorious “ghetto” neighbourhoods — East London’s *Docklands* and *Canary Wharf*, New York’s *Harlem*, Toronto’s *Corktown* and Vancouver’s *Downtown Eastside*, to cite only a few of the most infamous examples—now arguably exist at varying stages of (post-) gentrification, retaining only faint traces of the “gritty-ness” that once gave them their heterogeneous “character” (Caulfield, 1989).

Beginning in 2006 following a series of media-fuelled moral panics concerning methadone maintenance treatment (MMT) largely focussed on accusations of fraudulent billing practices on the part of a large chain of MMT clinics throughout Ontario, the community conflict surrounding the relocation of an MMT clinic into the rapidly gentrifying neighbourhood of Corktown on the periphery of downtown Toronto—formerly home to Toronto’s industrial immigrant working class—provides a telling example of the role of hipsters in gentrification and (socio-)spatial displacement. In discussing the dramatic demographic shift the neighbourhood was witnessing, one local resident detailed the working class origins of the area, describing its “radically changing” and “upwardly mobile” socio-economic characteristics with reference to “BMW’s, lawyers and professors” (Smith, 2010, 2014).

Framed as a product of ‘creative class’ urban planning strategies (Florida, 2002), other community opponents focused explicitly on the impact of arts-oriented organizations and artists in the redevelopment of the neighbourhood, attributed in large part to an adjacent industrial complex that was transformed into a “hub of creative class culture,” complete with allocated spaces for artist studios, theatre groups, a local micro-brewery pub, an upscale independent coffee shop and other “creative class” amenities (Smith, 2010, 2011, 2014).

Noting the arrival of “trendy, cool” businesses in the immediate area, other local business owners predicted that the methadone clinic and its service user population would eventually be displaced by the growing concentration of up-scale businesses, citing Starbucks as being emblematic of this trend¹¹.

In the first instance, therefore, hipsters are implicated in the displacement of urban spaces that were once the neglected, stigmatized domain of people who use illicit drugs. Because it

⁹ Both demographic acronyms, *yuppie* is an adapted abbreviation of “young urban/upwardly-mobile professional,” while DINK stands for “dual-income no kids.”

¹⁰ For an ethnographic account of “shooting galleries” in New York City—and a corresponding feminist critique—see Bourgois (1998) and Vitellone (2010).

¹¹ Here, see: Smith, 2010, 2011, 2014.

has become a pejorative term that is seldom (if ever) deployed as a tool of *self*-identification (Greif, 2010; Haddow, 2008), however, the hipster is often invoked to absolve oneself from processes and phenomena associated with gentrification. Drawing from Bourdieu (1984), Greif (2010d, p. 3) summarizes hipster sub-types according to their relative social class positioning, social mobility, and role in gentrification, revealing a diverse demographic range that may, by extension, mirror and reflect that of the harm reduction workforce. Here, while upper-middle class hipsters largely represent active agents of gentrification, financially precarious lower-middle class hipsters (not unlike their artist “shock troop” counterparts) are often simultaneously positioned as both catalyst *and* victim of gentrification, who are themselves displaced once the process is complete (Greif, 2010d; Ley, 2003). The inherently appropriating sub-cultural force of hipsterdom—and its recuperation by real estate speculators hot on their heels—however, is inextricably implicated in the displacement of (street-based) users, user neighbourhoods, and drug/service user-oriented space more generally.

Elucidating the seemingly anomalous relationship between artists, gentrification, and “hipness” in Vancouver’s Downtown Eastside (DTES), Rob Shier (2002, p. 15) writes:

The image of artists fleeing this dilapidated urban area like rats from a ship is ironic given their reputation as the shock troops of gentrification. Typically, artists form the vanguard of urban colonization. Cheap studio and gallery spaces in a city’s ‘problem’ area brings occupancy, and raises the perception of safety and hipness. In a few years, so the story goes, an influx of tertiary shops, boutiques, restaurants, renters and loft owners follow. An area’s vices, its drug dealing and petty crime, are [therefore] bullied out by an influx of capital.

Despite every effort by municipal planners, private sectors developers, and real estate speculators, Vancouver’s DTES has not followed this model, and as Shier (2002, p. 15) concludes, it in fact “appears to work in reverse.”

Citing organized opposition by a significant population of low-income residents¹², and aggressive expansion of the hyper-capitalist “black market” drug economy as the primary deterrents to redevelopment, contrary to Shier’s (2002, p. 16) projections, the DTES has more recently begun to show increasing signs of encroaching gentrification from all sides.

Here, in spite of arguments suggesting impediments to inner-city gentrification in Vancouver (Ley & Dobson, 2008), anecdotal evidence suggests that a plethora of galleries (re-)opened in the DTES between 2010 and 2012 (Ann Livingston, *Vancouver Area Network of Drug Users* [VANDU] co-founder, personal communication).

DISPLACEMENT #2: THE DISPLACEMENT OF DIRECT USER INVOLVEMENT IN HARM REDUCTION PRACTICE

A symptomatic expression of what I have termed the “*gentrification of public health*,” the second form of displacement perpetuated by harm reduction hipsters concerns the relative positioning of drug/service users, ‘peers’ or *people with lived experience* of substance use in

¹² (many of whom are also part of the area’s large illicit drug using community, and/or members of the *Vancouver Area Network of Drug Users* [VANDU], a group that is discussed in more depth in later section of this chapter; for further information regarding VANDU’s organizational structure, mandates, and achievements, see: Kerr et al., 2001, 2006 and VANDU, 2004, 2010).

all aspects and dimensions of harm reduction, including policy development, program implementation, service delivery, and evaluation (Cheng & Smith, 2009).

Here, a plethora of recent research suggests that drug/service users can and do play a critical role in the development and delivery of a diverse range of harm reduction interventions (Allman et al., 2006; Canadian HIV/AIDS Legal Network, 2005; Canadian Harm Reduction Network, 2008; Cheng & Smith, 2009; City of Toronto, 2005; Coyle, Needle & Normand, 1998; Friedman et al., 2004, 2007; Kerr et al., 2001, 2006; Latkin, 1998; Mason, 2006; Orme & Starkey, 1999; Ruefli & Rogers, 2004; Toronto Harm Reduction Task Force, 2003; VANDU, 2004, 2010). “At this point in history,” proclaims a 2010 manifesto produced by the *Vancouver Area Network of Drug Users* (VANDU, 2010, p. 1), “the question of how drug users are organized and represented [...] is decisive.”

Masking their relative positions of socio-economic mobility and privilege, many hipsters’ ostensible affinity with marginalized, socially vulnerable populations such as people who use drugs merely constitutes a superficial alliance. Conveyed through the deception of aesthetics, this supposed affinity constitutes little more than new source material for a pastiche of unmoored signifiers of socio-economic marginality divorced from their original political context. Here, as Haddon (2008) writes, hipster style is largely composed of “symbols and icons of working or revolutionary classes” that have been “appropriated by hipsterdom and drained of meaning.”

The recent cachet of harm reduction among hipsters and the corresponding deluge of hipster involvement in institutionalized public health, in other words, in/directly functions to displace users and peers as the central engine of harm reduction policy development, service delivery, research, and program evaluation, relegating people who use drugs to passive research subjects and other stigmatizing, tokenistic positions (Canadian HIV/AIDS Legal Network, 2005; VANDU, 2010).

Clearly demonstrating the persistent systemic stigma concerning people with lived experience of substance use among biomedical and public health authorities, an ethnographic anecdote from Vancouver’s DTES provides a telling case in point regarding the under-representation—and, in many cases, complete displacement and consequent absence—of drug/service users from institutionalized harm reduction policy and practice.

During a break in a conference I attended in Vancouver hosted by the University of British Columbia (UBC) in 2011, while walking down East Hastings Street, I serendipitously arrived in front of Insite, the first and only legally sanctioned supervised injection facility (SIF) in North America. Established as a scientific trial in 2003, the fate of Insite was contested by the federal Conservative government, who, following the completion of Insite’s “trial” stage, challenged the legal status of the facility in the Supreme Court of Canada. After weeks of legal arguments and expert testimony, however, in 2011 the Canadian Supreme court ruled against the federal Conservatives, in favour of institutionalizing the facility.

Having served as co-investigator for an SIF needs assessment study that was undertaken elsewhere in Canada, and conducting a thorough, evidence-based review of the scholarly, scientific literature concerning such services and facilities throughout the world, I spontaneously decided to conduct a self-guided tour of Insite¹³.

¹³ My tour of Insite took place while the facility’s fate was still being decided by the federal Supreme Court of Canada, immediately preceding the Insite benefit event described in the following section.

Glancing around the interior space of the facility while awaiting the registration necessary to enter the supervised injection area, I noticed that the injection stalls—composed exclusively of mirror and stainless-steel—were positioned in a perfect horse-shoe arrangement surrounding an elevated monitoring post that Fischer, Turnbull, Poland and Hayden (2004, p. 361) have referred to as the “*injec-ticon*.” In their investigation of SIFs as “governmentality” (Foucault, 1991), Fischer et al.’s (2004) reference to the “inject-icon” explicitly points back to Foucault’s (1977, 1980) writings on the *panopticon*, drawn from Jeremy Bentham’s theoretical model of prison architecture. Here, according to Foucault (1977, 1980) the ever-present threat of surveillance by prison authorities resulted in behavioural self-regulation and self-disciplining among the inmates.

Entering the central area of the facility, I noticed that behind the *inject-icon* sat two young Insite employees, one engrossed in checking her Facebook account on her desktop computer terminal, while the other leaned against the wall, unconsciously stroking his waxed handle-bar moustache while casually fiddling with his iPhone. *Why wasn’t there a paid user or “peer” on site?*, I silently wondered. Standing there drinking in the scene for another few moments, the answer to my absent-minded, rhetorical query became immediately, sickeningly apparent: hipsters have come to occupy most of the central positions of power within harm reduction, effectively displacing the direct involvement of people who use drugs, and at best engaging in superficial, tokenistic—and in some cases outright exploitive—forms of sub-contracted user consultation (Canadian HIV/AIDS Legal Network, 2005; Cheng & Smith, 2009; VANDU, 2010). Arriving at this revelation, I caught myself quietly muttering the words “*harm reduction hipsters*” under my breath. Looking up from her Facebook page, the young woman at the computer terminal behind the elevated “inject-icon” immediately stopped typing, turned to face me, and vehemently responded: “I am not a hipster.” Not unlike how running from the police is read or interpreted as a sign of guilt, however, proclamations such as this that served to deny one’s hipster status essentially connoted complicity (Greif, 2010d).

Given the rapidly increasing impetus for what is generally termed “(service) user involvement” in mental health and HIV policy discourse, this problematic directly calls back to the Canadian HIV/AIDS Legal Network (2005) position-paper-turned-global-drug-user-activist-mantra, entitled “*Nothing About Us Without Us*.” Even in the DTES, arguably Canada’s most infamous open drug scene and home to VANDU, undoubtedly the most accomplished and militant (quasi-?) autonomous user-driven organization in North America, however (Kerr et al., 2001, 2006; VANDU, 2004, 2010), users have been—and continue to be—displaced from positions of power by hipsters who espouse a social, spatial, and ideological affinity with all things “marginal,” while also actively propagating the institutionalized public health model of harm reduction as a “rational,” “pragmatic,” “amoral” response to the depoliticized biomedical vision of addiction-as-“disease,” a model or paradigm that actively serves to obscure, neglect, and moreover negate the very possibility for any form of socio-structural analysis, political interrogation, or cultural critique, as the notion of “addiction” is so neatly summed and sutured up inside the faulty neuro/chemical circuitry of the addicted subject (Courtwright, 2010; Keane, 2003; Miller, 2001; Reinerman, 2005; Roe, 2005; Smith, 2012b).

DISPLACEMENT #3: THE GENTRIFICATION OF PUBLIC HEALTH

Produced by the cumulative impact of the preceding hipster-driven forms of (socio-spatial) displacement, we therefore arrive at what has been alluded to throughout this chapter as the *gentrification of public health*, entailing the displacement and subsequent erasure of radical and/or oppositional politics from harm reduction discourse, policy, and practice, a symptomatic expression resulting from the global pandemic infection of the pathology paradigm for addiction research and treatment. As a culmination of drug/service users' successive *socio-spatial* displacements, the gentrification of public health is thus catalysed, enabled, and/or facilitated by hipsters' un/conscious role in promoting a sanitized, depoliticized form of harm reduction policy and practice far removed from its philosophical, praxis-driven origins as a radical, direct action oriented social movement (Roe, 2005; Smith, 2012b; Stoller, 1998). In order to adequately unpack this final—and arguably most significant—form of hipster-implicated displacement, I therefore make reference to one final ethnographic vignette.

While attending a conference in Vancouver in May 2011, I attended an event entitled *Health, Harm Reduction and the Law*. A benefit for the Insite Supreme Court challenge, the event was held at the recently completed Woodward's redevelopment, the symbolic heart of gentrification on the border of Vancouver's DTES (Sommers, 1998; Sommers & Blomley, 2002).

Arguably one of the most contested redevelopment projects in Vancouver's history, the former Woodward's department store was built in 1903, serving as both a preeminent downtown shopping destination and the focus of several large-scale labour riots during the early twentieth century (Sommers, 1998)¹⁴.

Site of one of the most militant housing squats in Canadian history in 2002 ("*Woodsquat*"), the recently completed redevelopment of the site was based on mixed-use and mixed-income planning principles, incorporating social housing, market rent condominiums, and academic facilities for Simon Fraser University (SFU) and the University of British Columbia (UBC).

Sitting in the Woodward's courtyard as the crowd gathered for the event, I glanced up at the ornate glass and steel structure and was immediately struck by a large public art piece adorning the interior wall of the courtyard, depicting what appeared to be a riot.

An unlikely site for a public symbol of the political violence that has intermittently erupted in the DTES over the course of the last century, I later learned that the photographic mural was completed by internationally renowned Vancouver-based artist Stan Douglas, representing a curious concession to the SFU School for Contemporary Arts. Depicting the Gastown riots of 1971, Douglas's (2008) *Abbott and Cordova, 7 August 1971* is, however, not the only project to take up the shifting and highly contested political geography of the DTES.

A photograph literally depicting *Every building on 100 West Hastings* street, the title of Douglas's 2001 photographic work is not only self-descriptive, but also evocative of both the gentrifying forces encroaching on all sides of the DTES, and the relentless creative-destructive redevelopment of the 'addicted city' of our 'narcotic modernity' more generally (Berman, 1982; Derrida, 1993; Smith & Derkson, 2002; Wild, 2002).

¹⁴ For a more detailed history of the symbolic significance of Woodward's as a central site of organized protest and resistance in Vancouver throughout the twentieth century see Sommers (1998).

Detailing the place of the DTES in the increasingly acute socio-spatial polarization of Vancouver, Shier (2002, p. 10) writes that “[w]ithin this enfolding sphere of civic entitlement and reimagination, the 100 block stands out in stunning relief,” demarcating a “shifting border” between “ruin and renovation” that “waxes and wanes across a number of social boundaries.”

Deriving similar inspiration from Douglas’s (2001) work, and grounded in the social impact of political-economic forces, in slightly more stark terms Sommers and Blomley (2002, p. 19-20) suggest:

The evident changes in the 100 block of West Hastings are inseparable from the deindustrialization of the downtown waterfront and the reorientation of the downtown economy toward tourism, information, and producer and consumer services. Nor can they be understood without taking into account the widespread gentrification and redevelopment of the old working-class residential neighbourhoods in and around the urban core, which, in turn, is bound up with new forms of inequality that come with the post-industrial economy.

The first public event held at Woodward’s since the site’s multi-purpose redevelopment was completed, *Health, Harm Reduction and the Law* drew a larger than expected crowd, and with a suggested \$10 (CDN) suggested donation, the auditorium quickly filled to capacity, forcing organizers to turn away the remaining line-up of mostly young, “progressive” looking, “hip” individuals stretching out the door. Settling into my seat as the stage was prepared I scanned the crowd, noting an unusually high prevalence of leather jackets, “sleeve” tattoos, skinny jeans, ironic facial hair, horn-rimmed glasses and vintage screen-printed t-shirts among the attendees.

As the evening’s speakers were introduced, a leaflet was distributed through the crowd by members of VANDU. Bearing the title *Manifesto for a Drug User Liberation Movement* (VANDU, 2010, p. 1), the opening paragraph read: “Our liberation will come when we have real power in decisions that affect us starting with, but not limited to, laws and policies having to do with drugs and drug use.”

Detailing VANDU’s major principles and aims, the document further asserted that the key to overcoming the “oppressive drug regime and realiz[ing] liberation for drug users” was fundamentally contingent upon the formation of local, national, and international “organizations of people who use drugs that are grassroots, democratic, relevant and effective”; in order to “ensure real self-representation,” the manifesto continued, such groups must clearly insist “that people who use drugs are the one’s to define the participation of people who do not” within the organization (VANDU, 2010, p. 2). As the presentation got underway, my adjacent colleague, a middle-aged British woman, leaned over with a genuinely perplexed look on her face and whispered, “*Who are all these people in the crowd?*” “*Harm reduction hipsters,*” I quietly replied before the curtains rose and the auditorium fell to a hush, yet my cryptic response only seemed to add to her confusion.

Discussing my initial ideas for this essay with several major international harm reduction advocates, from activists to academics, drug users to policy actors, a number of individuals presented the counter-argument that the “mainstreaming” of harm reduction, irrespective of the specific demographics that were mobilized and involved, could only be seen in positive terms. In other words, if harm reduction was becoming “hip,” cool, or culturally cachet, several colleagues insisted, it mattered little *who* composed the critical mass behind it’s growing momentum. The mainstream acceptance of harm reduction, I responded, was taking place at the expense of a series of mutually constituting social, spatial, and political

displacements that were not only fundamentally antithetical to—but also responsible for—the systematic displacement and erasure of the explicitly radical, direct action oriented, oppositional political origins, and founding anarchist spirit of hard reduction as first and foremost, a compassionate, human rights based, grassroots, bottom-up social movement. If hipsterdom had become the reigning (albeit recycled) sub/cultural identity of the early twenty-first century, I argued, the colonization of the harm reduction by the apolitical and depoliticizing phenomena of contemporary hipsterdom signalled the end of the movement as an overtly critical, structurally-focused political force. Implicated in not only the spatial displacement of users through processes of gentrification and the social exclusion of people with lived experience of substance use, dependence, and treatment from the policies, research, treatment, and harm reduction interventions ostensibly conducted in their interests (Cheng & Smith, 2009), hipsters and hipster culture are moreover actively complicit in the erosion of harm reduction's historical import as an explicitly political, user-driven force (Hunt & Stevens, 2004; Roe, 2005; Smith, 2012b; Stoller, 1998).

CONCLUSION: QUESTIONING RESEARCH MOTIVES/ALLIANCES AND (RE)MAPPING UNEQUAL DISTRIBUTIONS OF POWER IN A FLUID LANDSCAPE OF CONTROL

“This is a challenge to academics, policy experts and service providers,” proclaimed the *VANDU Manifesto for a Drug User Liberation Movement* (2010, p. 2):

... we do not want to be used as cheap labour, we do not want to be studied while we die, or be turned into clients while resources are given to ‘service’ agencies. We will not tolerate actions that exploit the labour, activist work, or experiences of people who use drugs.

As we simultaneously witness (1) the disappearance of physical urban spaces for drug/service users to congregate, inhabit, and socialize; (2) the displacement of direct, active, meaningful forms of drug/service user involvement and engagement in harm reduction policy development, service delivery, research, and program evaluation; and (3) the consequent depoliticization of the movement's explicitly radical, structurally-focused founding political philosophy, this chapter urges all researchers, policy actors, and front-line workers to heed these words. “Finally,” the *VANDU Manifesto for a Drug User Liberation Movement* (2010, p. 2) concludes with a tone of militancy that arguably represents the antithesis of hipster irony: “we expect responsible researchers, experts and academics to support us.” Borrowing from the explicitly radical, critical tone of VANDU's *Manifesto*, the question of how to meaningfully engage, support, and ally one's self with such a liberation movement without displacing, dissolving, diluting, or destroying the very people, places, and politics at its core, is the challenge that this essay has provocatively posed.

As the cumulative ethnographic anecdotes scattered throughout the chapter reveal, the only thing that is clear in terms of undertaking any such endeavour is that harm reduction's stated ‘user-centred’ mandate or orientation must no longer take the form of superficial, tokenistic—and in many cases outright exploitive—initiatives in self-congratulatory, surface-level ‘consumer involvement.’ Moving forward, in other words, instead entails relationships

firmly rooted in the notions of ‘collaborative autonomy’ and ‘indigenous inclusivity,’ both through mandating direct consultation and engagement with independent drug user organizations regarding the policies and programs that are ostensibly developed and implemented in their interest, and by allowing organizations run by and for people with lived experience to maintain their autonomy and independence, and thus clearly (re-)situating the fundamentally crucial importance of drug/service users’ lived, experiential knowledge in all aspects of harm reduction policy and practice (Cheng & Smith, 2009).

Chapter 503

ADDRESSING THE BOOTSTRAP MYTH: A PUBLIC HEALTH RESPONSE TO CHILDHOOD ADVERSITY

M. Grace Ryder, PhD

**CHILDREN'S CRISIS TREATMENT CENTER, PHILADELPHIA,
PENNSYLVANIA, USA**

ABSTRACT

A need exists to address childhood trauma and traumatic stress as a public health issue. The prevalence and impact of childhood adversity in our culture cannot be overstated. It is one of the primary roots of many of our more pervasive societal challenges including persistent poverty, health-risk behaviors, substance abuse, child abuse, and domestic violence, to name a few. Similar to other public health issues, efforts need to be placed on increasing public awareness, as well as effective prevention and treatment strategies. Efforts to increase awareness need to address societal attitudes, perceptions, and responses to childhood trauma throughout the lifespan. Specifically, the common belief that those impacted by trauma largely overcome adversity and persevere through the strength of their own character needs to be challenged based on what we know about trauma and recovery. Efforts must focus on public health messaging about the impact of trauma and building trauma-informed and trauma-responsive public and private sector systems whose policies and services recognize and respond to the impact of traumatic stress.

INTRODUCTION

The prevalence and subsequent impact of childhood trauma requires a public health response not unlike responses to other major health issues. Similar to other public health issues, efforts need to be placed on increasing public awareness, as well as effective prevention and treatment strategies. This chapter will review the prevalence and impact of

childhood trauma, address the need to change societal perceptions and attitudes about those impacted by trauma, and define ways to approach the issue from a public health perspective.

ADVERSE CHILDHOOD EXPERIENCES (ACEs)

The Adverse Childhood Experience (ACE) Study, a well-documented and independently replicated study originating from a collaboration between the Centers for Disease Control and Prevention (CDC) and Kaiser Permanente's San Diego Medical Center, demonstrates that certain experiences during childhood such as child maltreatment are major risk factors for the leading causes of illness and death as well as poor quality of life in the United States (U.S. Centers for Disease Control and Prevention, 2015). The researchers found a strong relationship between the breadth of exposure to abuse or household dysfunction during childhood and multiple risk factors for several leading causes of death in adults (Felitti et al., 1998). It is critical to understand how some of the worst health and social problems in our nation can arise as a consequence of adverse childhood experiences. Realizing these connections is likely to improve efforts towards prevention and recovery.

The ACE Pyramid (Figure 1) represents the conceptual framework for the study. The study was designed to provide data that would help answer the question: "If risk factors for disease, disability, and early mortality tend to cluster, that is, persons who had one risk factor tended to have one or more other risk factors too, what influences precede the adoption or development of them?" By addressing this question, the researchers provide scientific information that is useful for developing new and more effective prevention programs.

From the U.S. Centers for Disease Control and Prevention, 2014.

Figure 1. ACE pyramid.

The ACE Study uses the ACE Score, which is a total count of the number of adverse childhood experiences reported by participants. The ACE Score is used to assess the total amount of stress during childhood and has demonstrated that as the number of ACEs increase, the risk for the following health problems increases in a strong and graded fashion:

Alcoholism and alcohol abuse	Chronic obstructive pulmonary disease (COPD)
Depression	Lower health-related quality of life
Illicit drug use	Ischemic heart disease (IHD)
Liver disease	Adolescent pregnancy
Intimate partner violence	Multiple sexual partners
Sexually transmitted diseases (STDs)	Smoking
Suicide attempts	Unintended pregnancies
Early initiation of smoking	Early initiation of sexual activity

Stated most clearly, the ACE Study identified the “scientific gaps” linking ACEs to risk factors and the risk factors to short-term and long-term health and social consequences.

More recent studies confirm and expand on the findings of the original study. For example, the Philadelphia ACE Task Force was formed in 2012 with an interest in examining the prevalence and impact of ACEs in Philadelphia, a city with a socially and racially diverse population. The Philadelphia Urban ACE Study (2015), which was funded by the Robert Wood Johnson Foundation and conducted by the Public Health Management Corporation (PHMC) for the Institute for Safe Families and the ACE Task Force, collected data from Philadelphians regarding adversity that they faced. The questions developed for this survey expanded on the original questions from the ACE Study to include experiencing or witnessing community violence. These new questions were the first extensive survey of this kind specifically for an urban setting. The survey found a higher prevalence of original ACEs than found in previous studies. Furthermore, the study found that 40.5% of Philadelphia adults, while growing up, witnessed violence, which includes seeing or hearing someone being beaten, stabbed, or shot. In all, over 37% of Philadelphia respondents reported four or more ACEs. The findings from this study suggest the need for services that address the unique environmental stressors experienced in urban neighborhoods in order to mitigate their impact on individuals and prevent ACEs. The ACE Task Force, which is currently housed at the Health Federation of Philadelphia, continues to actively work to develop a response to these issues.

RISK AND PROTECTIVE FACTORS

The percentage of people in our society impacted by the connection between ACEs and poor health outcomes necessitates an examination of both risk and protective factors. Risk factors refer to the stressful conditions, events, or circumstances that increase an individual’s, family’s, and/or community’s chances for poor outcomes. Protective factors are conditions of individuals, families, and communities that mitigate risk, promote well-being, and reduce the risk for negative outcomes (Child Welfare Information Gateway, 2014).

Parental risk factors include but are not limited to a caregiver’s lack of parenting knowledge and skill in specific areas such as child development; a caregiver’s own adverse childhood experiences; and characteristics such as young age, low education attainment, and low income. Family risk factors include social isolation, domestic violence, parental stress, and poor parent-child relationships. Community risk factors include community violence,

concentrated neighborhood disadvantage such as high poverty and unemployment rates, and poor social connections.

Although critical to our understanding of effective prevention and intervention strategies, protective factors have not been studied as rigorously as risk factors. However, the Centers for Disease Control and Prevention (CDC, 2015) reports scientific evidence for supportive family environments and social networks. Other potential protective factors include nurturing parenting skills, stable family relationships, access to health care and social services, and caring adults outside the family who can serve as role models and mentors.

RESILIENCY

As more attention is being paid to ACEs and means to reduce risk and enhance protective factors, the concept of resiliency has more strongly emerged in the literature. Resilience is the process of adapting well in the face of adversity, trauma, and tragedy; it means “bouncing back” from difficult experiences (American Psychological Association, 2014). Resiliency in children is said to be the ability to master normative developmental tasks despite experiences of significant adversity (Luther, Cicchetti, & Becker, 2000). By definition, resiliency should be promoted and admired in those who exemplify it. However, this chapter will focus on the misuse of the term as it applies to individuals who experience significant adversity during childhood.

“Pulling yourself up by your own bootstraps” refers to the imagined feat of lifting oneself off the ground by pulling on your own bootstraps. This impossible task exemplifies the achievement of getting out of a difficult situation only by one's own efforts. It is the belief that rugged individualism, individual grit, extraordinary self-reliance, or some inborn, heroic strength of character can triumph over trauma. This myth is perpetuated and even exploited in modern culture through mass-marketed movies and television where the underdog is cheered for his/her innate strengths in the face of adversity.

One of the many dangers of this ideology, the ideology that overcoming the odds is simply a matter of individual motivation or grit, is that the failure to excel is perceived as the fault of the individual, and “blaming the victim” becomes part of the narrative (Center on the Developing Child at Harvard University, 2015). This, in turn, not only allows us to abdicate responsibility for those who have fallen but also releases us from the responsibility of creating opportunities for people to overcome adversity.

Success stories of people overcoming adversity are ubiquitous the world over. Through these stories, we learn about the complexity of trauma and recovery. Examples include Malala Yousafzai, the Pakistani activist, Nobel peace prize recipient, and author of *My Name is Malala* (Yousafzai & Lamb, 2013), who faced insurmountable barriers and trauma during her childhood; Louis Zamperini, subject of the book “Unbroken” (Hillenbrand, 2010) and a World War II veteran who endured years of torture and humiliation after being captured; and Charles Blow, author of “Fire Shut Up in My Bones: A Memoir” (2014) who suffered sexual abuse, extreme poverty, and other adversities as a child and went on to become a respected journalist. Recognizing the strengths and resiliencies in others is indeed important, and individual strengths are necessary to overcome trauma. However, a need exists to develop a

public health response to trauma, a response built on the understanding that it takes more than true grit to overcome adversity.

The narrative needs to change. Science debunks the bootstrap theory. Science tells us that the reliable presence of at least one supportive relationship and multiple opportunities to develop effective coping skills are the essential building blocks for the capacity to do well in the face of significant adversity (Center for the Study of Social Policy, 2015). These relationships begin in the family but also include neighbors, providers of early care and education, teachers, social workers, doctors, and coaches, among others. A deeper examination of the lives of each individual able to persevere in the face of adversity, including those in the previous paragraph, reveals the existence of individual, family, and community protective factors. What is critical to this discussion is the process by which one develops resiliency, as opposed to whether or not a person is resilient. For example, research shows us that children's individual strengths help them adapt only under conditions of low stress, not high levels of toxic stress (Jaffee, Caspi, Moffitt, Polo-Tomas, & Taylor, 2007). The protective effects of children's individual strengths must be understood within the context of their life circumstances. Furthermore, data suggest that efforts must also focus on parents' well-being and the conditions of the neighborhoods in which they live in an effort to understand needs and intervene successfully (Jaffee et al., 2007).

Resilience is best understood as a social construct rather than an individual trait. Resilience is the result of multiple interactions among protective factors in the social system. Protective factors constitute the foundations of resilience and evidence suggests they are cumulative in nature. Understanding resilience as a social construct makes explicit that it is more likely to occur when we provide access to needed services, supports, and resources (Fox, 2015).

The Center on the Developing Child at Harvard University (2015) illustrates resilience through the concept of a balance scale or, in a child's world, a seesaw (Figure 2). Experiences that can result in toxic stress, such as repeated or chronic exposure to violence, poverty, or maltreatment, pile on the negative side of the scale. Positive influences that can help make significant stress tolerable, such as supportive relationships, skill-building opportunities to develop coping skills, and practice dealing with manageable challenges, tip the scale the other way. Resilience is evident when positive experiences tip a person's "scale" toward positive outcomes despite the weight of negative experiences. Understanding all the influences that might tip the scale in the positive direction is critical to devising more effective strategies for promoting healthy development in the face of significant adversity. Continuing with the concept of the balance scale or seesaw, the fulcrum can represent a child's individual predispositions (Center on the Developing Child at Harvard University, 2015). Advances in science are now showing us that the position of the fulcrum is not fixed. The continuing accumulation of positive and negative experiences over time actually influences the child's mental and physical constitution and consequently has the power to slide the fulcrum in either direction. Furthermore, developmental trajectories begin in infancy but do not fully mature until age 25 to 30 years. Just as protective factors serve children well, opportunities to learn and develop skills are critically important capabilities for the adults who care for them, and can be strengthened through coaching and practice. Identifying and making available those protective factors that are shown to help children overcome adversity need to be the focus of our attention, our policies, and our resources.

Figure 2. Resilience is evident when positive experiences counterbalance negative ones to tip a person's "scale" toward positive outcomes.

The Center for the Study of Social Policy's Strengthening Families: A Protective Factors Framework (2015) is a research-informed approach to increase family strengths, enhance child development, and reduce child abuse and neglect. Its focus is on engaging families, programs, and communities in building five protective factors:

- Parental resilience
- Social connections
- Knowledge of parenting and child development
- Concrete support in times of need
- Social and emotional competence of children

A literature review and expert consultation project commissioned by the Administration on Children, Youth and Families (Child Welfare Information Gateway, 2014) found that at the individual level the protective factors with the most evidence to help children overcome adversity include opportunities to build self-regulation skills, relationships skills, and problem-solving skills. At the relationship level, protective factors with the most evidence include opportunities to build parenting capacities, positive peer interactions, and multiple interactions with caring adults. At the community level, protective factors with the most evidence include opportunities to build responsive community environments, positive school environments, and economic opportunities.

The interplay between child and environment is bidirectional. The sooner we intervene on this bidirectional chain, the better our chances of fostering positive adaptation across domains. We need to support efforts of multisystem interventions that target multiple levels of the child's world including parent well-being and neighborhood factors. Stated most directly, the combination of adaptive skill-building, supportive relationships, and positive community experiences constitutes the foundations of resilience (Center on the Developing Child at Harvard University, 2015). These foundations are built through the creation of trauma-responsive environments.

A MENTAL HEALTH RESPONSE

This chapter thus far has laid out an argument for creating opportunities for those impacted by trauma to develop resilience. It is by creating the context for recovery that those impacted by trauma may gain an understanding and learn skills necessary to thrive. Pockets exist throughout the country that focus on creating these contexts for recovery or trauma-informed systems. A trauma-informed system, organization, or program realizes the widespread impact of trauma and understands potential paths for recovery; recognizes the signs and symptoms of trauma in others; responds by fully integrating knowledge about trauma into policies, procedures, and practices; and seeks to actively resist re-traumatization (SAMHSA, 2015).

In order to exemplify some of this work, the city of Philadelphia, Pennsylvania, and more specifically a children's mental health agency in Philadelphia, Children's Crisis Treatment Center (CCTC), will be illustrated. CCTC is a private, nonprofit agency that specializes in providing mental/behavioral health services to children and their families. For over 40 years, CCTC has developed and implemented innovative ways of helping children as young as 18 months old and their families cope with obstacles that interfere with their emotional, social, and cognitive growth. Services and programs are provided at the center as well as in the home, community, and schools.

CCTC is dedicated to addressing the impact of childhood abuse/neglect and traumatic events that can affect childhood development. Our approach to providing behavioral health services to children and their families revolves around an understanding of the impact of adverse life experiences. Despite tremendous challenges, children heal from psychological injuries. Through partnerships with families, schools, and communities, CCTC creates the contexts in which this healing may occur.

With a staff of more than 450, CCTC serves over 3000 children and families annually. CCTC is recognized for its expertise in the areas of child/family mental health, trauma, and school-based services. Such acknowledgements reflect CCTC's leadership role in the children's behavioral health services community.

CCTC has a strong history of bringing focus to the impact of trauma. In the late 1980s CCTC developed one of the first programs in Philadelphia offering trauma-focused treatment for children and their families impacted by abuse, neglect, and other adverse childhood experiences. This expertise primed the organization to further educate leadership, staff, and other stakeholders on the impact of trauma.

In 2006, CCTC formalized its commitment to trauma-informed care and began implementing the Sanctuary Model. Sanctuary is an organizational change model that integrates trauma theory with the creation of therapeutic communities which provide safety for both those served and the staff who serve them (Bloom, 1997). The model organizes how we talk about treatment, fosters a shared language, promotes consistent contact with team members, children, and families, and keeps a focus on the impact of recurrent stress as well as growth and change (Sanctuary Institute). The Sanctuary Model promotes a perspective that asks: "What's happened to you?" rather than "What's wrong with you?" when organizing goals and assessing strengths and challenges. CCTC embraces the Sanctuary Model and is dedicated to creating a trauma-informed culture of open communication, nonviolence,

emotional intelligence, social learning, shared governance, social responsibility, and growth and change which encompass the values of the Sanctuary Model.

CCTC integrates trauma-informed care into its treatment approach. Examples are: including trauma histories in all biopsychosocial evaluations, viewing child and family challenges through a trauma lens, understanding that many of the negative behaviors that children exhibit are attempts to cope with their traumatic experiences and intervening accordingly, educating children and families on the impact of trauma, and ensuring that children receive trauma-focused treatment when indicated. Children and families participating in services develop Safety Plans to support their use of coping strategies during times of stress/crisis. Treatment plans, progress notes, and all other service documentation are embedded with trauma-informed language to ensure that the focus of services is not only on trauma but also on recovery and resiliency. CCTC's day treatment programs facilitate Sanctuary Psychoeducational groups, which educate children on the impact of trauma in a developmentally tailored way and teach them coping strategies. Caregiver services are infused with trauma-informed principles and techniques. For example, members of CCTC's family advisory group are ambassadors of the Sanctuary Model during their interactions with peers at CCTC and in their communities.

All programs at CCTC support the trauma-informed care approach and a resiliency framework. One such program is the Filial Parenting Program, a group-based therapeutic approach that CCTC has offered for over 10 years. The program is based on the Filial Therapy model (Van Fleet & Guerney, 2003) and infused with the Sanctuary (Bloom, 1997) and Incredible Years (Webster-Stratton, 1998) models. Each 14-week group cycle is led by two master's level clinicians and consists of a structured curriculum that includes the teaching and modeling of specific parenting skills, the practicing of these skills by caregivers, and the creation of a therapeutic community that encourages peer support through discussion and feedback.

Filial Therapy is a research-supported model that emphasizes the parent-child relationship as a means of alleviating child and/or family difficulties. Parents/caregivers learn to conduct a special type of play session with their children. Play is the natural language of children and is therefore an excellent medium for parents/caregivers to engage their children in order to enhance their relationship with them. Parents/caregivers learn to be more aware of their children developmentally, emotionally, and relationally. The Incredible Years parent training is a series of evidence-based interventions focused on strengthening parenting competencies in order to promote children's social and emotional competencies and reduce conduct problems. The foundation of CCTC's Filial Parenting Group is grounded in the application of four Filial Therapy skills and further supported by Incredible Years techniques that are introduced, discussed, modeled, and practiced throughout the 14-week cycle.

During the weekly group sessions, facilitators work with each parent/caregiver individually and in groups so that they can begin learning and practicing the skills and techniques. Initially sessions are held without the child present as parents learn the skills. Structured childcare is provided to the identified child as well as siblings in order to alleviate barriers to treatment participation. Once skills are learned, parents/caregivers then have practice sessions with their child with guidance from the facilitators. They are given supportive feedback and enhanced practice in order to gain mastery. Finally, parents/caregivers are given a complete kit of toys that they will use at home for individual "special playtime," initially with the child enrolled in the program but eventually with all of

their children. During the group experience, parents/caregivers are asked to practice the special playtime sessions at home and then return to the group to discuss the experience with the facilitators and their peers in order to further refine their skills. Also included in these sessions are discussions on how to generalize the principles to everyday life. The Sanctuary Model is embedded in the group throughout each weekly session and includes the use of the Sanctuary Community Meeting, which supports the development of a therapeutic community, and Safety Plan development, which supports the learning and practice of emotion management and coping skills.

Outcome measurement is an integral part of the Filial Parenting Program. Pre- and post-test surveys using the Adult-Adolescent Parenting Inventory and Parent Relationship Questionnaire are completed by caregivers. Data analysis demonstrates improvements in most parenting areas assessed, with significant improvement in parent/child attachment, parental involvement, parent expectations, parenting confidence, relational frustration, and attitudes on corporal punishment.

The Filial Parenting Program is an excellent example of creating a trauma-informed context in which healing may occur. Caregivers who participate in the program often present with multigenerational histories significant for adversity including child abuse, domestic violence, poverty, and homelessness, which continue to manifest in their daily lives. Despite these challenges and as the data supports, participants respond to a strengths-based approach that focuses on building protective factors including nurturing parenting skills, a stronger parent/child relationship, and peer support.

CONCLUSION

A public health response to trauma is not only necessary but critical to address the prevalence and impact of trauma. Healing does not only occur in treatment settings. The process of creating trauma-informed organizations is not exclusive to mental/behavioral health agencies but may include any type of organization, such as government-funded and -administered entities where many of the decisions that impact those affected by trauma are made. Examples include public utilities, courts, and schools.

The challenge before us is how to create trauma-informed systems and communities that work together to mitigate risk and strengthen protective factors. The Center on the Developing Child at Harvard University (2015) recommends the development of frameworks that integrate policies and practices across economic, education, health, and social sectors that can collectively reduce adversity and build our capacity to address adversity when it happens. An approach using a unified, trauma-informed, science-based framework could identify the best strategies for coordinated public-private partnerships to implement together. Strategies that build child and caregiver capacities work best when they are integrated within complementary policies across sectors that collectively lower the burden of stress on families due to the often interrelated threats of poverty, crime, mental illness, substance abuse, discrimination, and community violence.

Examples include but are not limited to the following:

- Public and private-sector entities can become trauma-informed, including but not limited to mental/behavioral health systems/providers, school districts, child welfare, juvenile justice, and court systems. The understanding that many of the struggles people internalize and externalize are rooted in trauma can dramatically transform the way services are delivered and their impact.
- Enhance efforts to hasten the research-to-practice pipeline. For example, interventions based on advances in brain research can have an immediate benefit on the resiliency of those impacted by trauma.
- When poverty-reduction policies require parents to work, we need to also assure parents' access to affordable, high-quality child care in order to promote both adult economic self-sufficiency and developmentally supportive experiences for their children (Center on the Developing Child at Harvard University, 2015).
- School settings can provide a range of opportunities for the development of knowledge, cognitive skills, and self-regulation abilities, all which enhance children's capacity to deal with adversity (Center on the Developing Child at Harvard University, 2015). School systems can address emotional development alongside cognitive development, given the fact that learning and self-regulation skills are inextricably linked. Behavioral health services can be integrated within schools to increase children's access to needed prevention and treatment services.
- Equip early-childhood programs with the high-quality tools and resources to address the impact of adversity. Young children are often asked to leave early-childhood programs for manifesting behaviors that represent the very reasons they need the program.
- Child welfare and mental health professionals can collaborate to focus on opportunities to restore family relationships and build the capacities that underlie resilience.
- Children's physical and behavioral health care can be integrated to increase families' access to and engagement in needed treatment.
- Parenting centers that offer evidence-supported, trauma-informed services can be integrated into existing community-based organizations, making parenting support universally available.
- The Strengthening Families Framework (Center for the Study of Social Policy, 2015) can be implemented throughout child- and family-serving systems to unify efforts to lessen adversity and build resilience.

Efforts must begin at building trauma-informed systems in which all parties involved recognize and respond to the impact of traumatic stress on those who have contact with the system including children, caregivers, and service providers. Agencies, programs and services within such a system infuse and sustain trauma awareness, knowledge, and skills into their organizational cultures, policies, and practices.. This process begins with leadership who promote and model an organization culture that recognizes the value of a trauma-informed framework on not only those who the organization serves but those who serve them.

We are who we are because we drink from wells that others dug and warm ourselves on fires that others struck.

- Ancient Celtic quote

ABSTRACT

Nigeria is a big, important and diverse country with many potentials and problems. It is a major oil and gas producer with unique vulnerabilities. It has the potential for rapid and robust economic development given its oil and other resources and its diversity of ecosystems. A major threat to the future of Nigeria is environmental damage. The ubiquitous nature of heavy metals, in Nigeria is very worrisome; it can be encountered in every sphere of life and environment. They occur naturally in the soil, solid minerals, food, also from industrial process and consumer products (locally and imported), electrical/electronic/automobile, pharmaceuticals, cosmetics, paints, etc. They are found at hazardous and domestic dump sites, in crude oils, agro-allied chemicals. It is distributed by water, air and fugitive dust, bio-accumulated by man, animals, plants, fish and other aquatic animals and plants. Heavy metals may enter the human body through food, water, air, absorption through skin and gut. Serious health problems such as headache, malignant cancer, severe abdominal pain, vomiting, diarrhea, fever, fatigue, loss of appetite, birth defect, mental retardation, hyperactivity, liver and kidney damage etc., are associated with heavy metal toxicity, all these and many more health challenges

* Corresponding Author's Email: johnduka2000@yahoo.co.uk; Tel: +234-07039541583.

that may be associated with heavy metal toxicity are increasing in Nigeria. In all these children may likely be more vulnerable.

Keywords: heavy metals, varied sources, ubiquitous distribution, environmental pollution, increasing health challenge, public health risks

INTRODUCTION

Nigeria is situated on coordinates 9.0820°N and 8.6753°E, the main latitude and longitude is 10°N and 8°E, with a total land area of 923,768sq km and an estimated population of 150m people. It is located in West Africa and shares land borders with the Republic of Benin in the west, Niger and Chad in the north, Cameroon and its southern coast lies on the Gulf of Guinea on the Atlantic Ocean. It is a big, important, diverse country with many potentials and problems. It is a major player in world's oil and gas activities, with huge proven reserves of solid mineral and agricultural resources. The exploitation of these resources has brought about environmental damage and uneven distribution of pollutants such as heavy metals amongst major environmental components (air, water and soil).

"Heavy metals" have been variously defined differently by several authors in different scientific literatures, it has been defined in terms of density (specific gravity); in terms of atomic weight (relative atomic mass); in terms of atomic number; defined based on other chemical properties such as dense alloys, intermetallic compound, metallic elements of relative high molecular weight; defined based on toxicity and non-chemical definitions used before 1936 such as guns or shot of large size (Ogilvie, 1884) and great ability (Williams, 1930). There are also several sub-definitions, with references summarized by Duffus (2002). Although, it has been established that the term "heavy metal" has not been defined by any authoritative body such as IUPAC, over the years, till date, it has been conveniently used in scientific literature, sometimes it has been used interchangeably with metals or trace elements (Zhang and Hqo, 2009; Ferreira-Baptista and De-Miguel, 2005) and it will be adopted in this study. Therefore, "heavy metals" are chemical elements with a specific gravity (density) that is at least 5 times (5x) the specific gravity of water. The specific gravity of water at 4°C is 1. Simplified definition states that specific gravity is a measure of density of a given amount of a solid substance when it is compared to an equal amount of water. Well known toxic metallic elements with a specific gravity that is five (5) or more times heavier than that of water are arsenic (5.7,) cadmium (8.65), iron (7.90), lead (11.34), Mn (7.42), Co (8.90), Ni (8.90), Cu (8.94), Ag (10.50), Au (19.30), Zn (7.10), Hg (13.60), V (6.11), Cr (7.19), etc., (Liptrot, 1983). There are 35 metals that are important because of occupational or residential exposure; 23 of these are the heavy elements or "heavy metals": antimony, arsenic, bismuth, cadmium, cerium, chromium, cobalt, copper, gallium, gold, iron, lead, manganese, mercury, nickel, platinum, silver, tellurium, thallium, tin, uranium, vanadium, and zinc (Glanze, 1996). In small quantities; certain heavy metals are essential for a healthy life. Some, such as (iron, copper, zinc, manganese) are referred to as the trace elements. These elements, or some form of them, are commonly found naturally in food stuffs, fruits and vegetables, and in commercially available multivitamin products. If heavy metals are not metabolized by the body, they accumulate in the soft tissues and become toxic. They may enter the human body through food, water, air or absorption through the skin when they come in contact with

human body through agricultural practices, manufacturing, pharmaceuticals, industrials, or residential settings. Adult exposure to metal toxicity is mainly through industrial activities while ingestion is the most common route of exposure in children. Most children may develop toxic levels from the normal hand-to-mouth activity of small children who may come in contact with contaminated soil or by actually eating objects that are not food (Dupler, 2001). A compilation has been made of 120 occupations e.g., auto mechanics, painting, printing, welding etc. that involves exposure to heavy metals (Wallace and Cooper, 1986). Other economic or occupational activities that may lead to metal exposures in adults include industrial activities like oil and gas activities, mining, smelting, refining and manufacturing processes and earth works such as road construction. Consumable products such as food drinks (Onianwa et al., 1999), pediatric syrups (Nduka and Orisakwe, 2009; Orisakwe and Nduka, 2009), canned and non-canned beverages (Maduabuchi et al., 2006), packaged water (Orisakwe et al., 2006), herbal remedies (Obi et al., 2006) and cosmetic products (Nduka et al., 2015) are veritable sources of heavy metal, non-consumable goods also contain appreciable high amount of metal element. Inhalation of fugitive dust or ingestion of road side soil/dust can predispose an individual to metal poisoning (Nduka and Orisakwe, 2010; Kakulu, 2003).

Other common routes of exposure are during a radiological procedure, from inappropriate dosing or monitoring during intravenous (parenteral) nutrition and from a broken thermometer. Geophagia-soil eating habit among children and pregnant women reported at Nnewi, South-eastern Nigeria can be a veritable means of exposure to heavy metal in Nigeria (Orisakwe et al., 2004). Acute poisoning is more likely to result from inhalation or skin contact of dust, fumes or vapours, or materials in workplace. However, lesser levels of contamination may occur in residential homes, especially in older homes with lead paint or old plumbing (IOSHIC, 1999). Heavy metals are dangerous because they tend to bio-accumulate in a biological organism over time compared to the chemical concentration in the environment. Metallic compounds accumulate in living things anytime they are taken up and stored faster than they are broken down (metabolized) or excreted and these leads to health impairment. Toxicity of heavy metal can result in significant illness and reduced quality of life (Ferner, 2001). This work is to remind policy makers in Nigeria that our country is under serious heavy metal pollution and that it is a threat to the health of future generations.

SOURCES OF HEAVY METALS IN NIGERIA

Solid Minerals

Though Nigeria is well known for its crude oil and gas reserves, little is known of its huge solid mineral deposits. That Nigeria is endowed with abundant mineral resources is stating the obvious, the minerals include (1) Limestone deposit which exist throughout the country. It is on record that Nigeria has over 8000 million tonnes of proven reserve of limestone deposits and these deposits far exceed requirements of the cement industry (Olaniyan, 1994). (2) Tin and columbite these are the principal metalliferous mineral exported from Nigeria. The country began refining its own tin in 1961 and exports refined tin mineral metal of 99.9 percent grade. (3) Iron ore-about 400 million tones of good quality iron

ore deposits have been discovered at Itakpe, near Okene in Kogi State, other deposits of iron ore with an average iron content of 40 to 50 percent are also found near Niger, Benue and Enugu States. (4) Lead-zinc-the Nigerian lead-zinc deposits extend continually for about 560 km in a narrow belt in Ishiagu, Abakalike in Ebonyi State and Bende area of Abia. (5) Gold-Gold is also available in Nigeria. The bulk of it is found in Sokoto, Niger, Kogi and Osun States. (6) Marble-this is found mainly in Kogi, Oyo and Niger State. (7) Stone is found in most parts of the country and it is extensively quarried and used for building purposes, roads, rail ballast, dam foundations and harbour works, (8) Zircon-quantities of this mineral are found in some rivers and streams in Nigeria and it is extracted as a by product of tin-columbite mining in Plateau state (9) Coal- is of note that Nigeria is the only West African country that produces coal. Its major coal mines are located in Enugu and Kogi States (<http://www.nigerianembassy-chile.org/nigeria/xgeography.shtml>) (10) other major minerals abundant in Nigeria include Tantalite, shale, non-ferrous metals, such as copper, aluminum, ferro-alloy metals include manganese, chromium, nickel, tungsten, cobalt, vanadium and molybdenum, gold, silver, platinum, antimony and cadmium (Obienusi, 2004). Since heavy metals are natural components of the Earth's crust, a single metallic or non-metallic ore can contain few or several of these metals in association (Oyinloye, 2004; Aneke, 1992), activities such as quarrying, mining and construction releases these metals into the atmosphere and it is inhaled by man, others settle on surface water, farmlands, and buildings and on our skin. Ako et al., (2014), reported that soil samples from and around Luku artisanal gold mining Minna, Niger State were enriched with Pb, Cd, Hg and Ag. Mining can only take place where minerals are present and economically viable. The general importance of the mining sector has been documented to include foreign exchange, employment and economic development (Nwajiuba, 2000; Obaje and Abaa, 1996). In Nigeria, minerals are extracted by unskilled and illiterate artisans in addition to simple and crude implement and these sometimes regarded as informal sector and therefore outside the legal and regulatory frame work (Azubike, 2011). Toxic heavy metals are released into the environment, posing serious health risks to the miners, family members and to the general populace. Acidic rains can also breakdown soils and soil/clay matrix and release heavy metals into streams lakes, rivers, and groundwater.

Crude Oil

Crude Oil consists of hydrocarbons with carbon and hydrogen in proximate ratio of 1:6 by weight (O' Donell, 1975) and other related inorganic metals. Amongst these constituents are sulphur, nitrogen and oxygen and trace metals. Nigeria's crude oil is known to contain varying proportions of heavy metals (Achi and Shide, 2004; Nwadinigwe, 1984; Nwadinigwe and Nworgu, 1999). Over sixty metals have been identified in crude oils with vanadium (V) and nickel (Ni) as the most abundant (Tiratsoo, 1973), Metallic components in crude oils occurs as metalloporphyrin chelates, transition metal complexes, organometallic compounds, carbonyl acid salts of polar functional groups and colloidal minerals (William and Roberts 1967, Lewis and Sani 1981). The abundance of certain trace metals, especially Ni and V in crude oils, is geo-chemically significance and provides information on the origin and maturation problems. Petroleum has been classified on the basis of wax and asphalt contents (Lewis and Sani, 1981), or on the basis of concentrations of trace metals content, others on

the basis of vanadium-nickel ratio (Punanova et al., 1994). Most trace metals are indigenously associated with the oil during formation whereas some trace elements are introduced into the oils during transportation, from oil wells to processing sites, storage tanks or processing equipment (Achi and Shide 2004).

Refuse Dumps

Most Nigerian cities are littered with refuse dumps with many domestic and sundry wastes. A typical refuse dump in Nigeria comprises wastes like clothing materials, beverages and food can, glass wares, worn-out tires, foods and waste papers, pharmaceutical and chemical containers, tobacco and match sticks and packets, cow dungs and poultry litter, wood and furniture wastes, metal scraps and aluminum foils, vegetable and food residue, batteries, exhaust pipe, water pipes, polymeric materials and agro-chemical containers. (Nduka et al., 2006); it is a known fact that organic compounds are associated with heavy metals, HEME a coloured pigment of haemoglobin called ferroprotoporphyrin contains iron as its central element (Hayid, 1991), haemocyanins found in molluscs and arthropods contains copper, both alcohol dehydrogenase found in horse liver and carboxypeptides present in pancreatic juice of man contains zinc, haemovanadins- an oxygen carrier in sea squirt contains vanadium. Vitamin B₁₂ also called cobalmine because of its tightly bound cobalt. Organotin compounds widely used as insecticide and fungicides while copper arsenate used as wood preservative gives rise to tin and arsenic respectively (Wentz, 1989). Since these organic or inorganic compounds that contain heavy metals are common at refuse dump sites in Nigeria, following favorable weather condition, they degrade and decompose releasing these toxic metals into the environment. We have previously reported high concentration of heavy metal in soils at refuse dump sites (Nduka et al., 2006).

Electronic and electrical wastes are veritable sources of heavy metals in Nigeria, because of unhealthy importation, an estimated 500 shipping containers loaded with second hand electronic equipment are brought into Nigeria through Lagos port every month, each container can be packed, on average with a load equal in volume to 800 computer monitors or central processing units (CPUs) or 350 large TV sets. Experts estimate that between 25% to 75%, of these materials are useless or irreparable junks. This is a problem, because “e-waste” can be toxic, much of it is loaded with potentially toxic metals including lead, copper, cadmium and mercury. This is bad for a country with economy almost tending to depend on leftovers (Schmidt, 2006): Iloh (2007) established that soils sampled close to old transformers have elevated levels of mercury. The values keep increasing as one move further close the transformers.

Industrial Processes and Products

Most heavy metals or their compounds find useful application in manufacture of industrial and home goods and in sundry economic sector. Arsenic is released into the environment by the smelting process of copper, zinc and lead as well as by the manufacturing of chemical and glasses. Lead is used for manufacturing batteries, cable covering, plumbing,

ammunition, fuel additives, PVC, plastics, x-ray shielding, crystal glass production, pencils and fuel additives. Like arsenic, cadmium is a by product of the mining and smelting of lead and zinc, it is used in nickel-cadmium batteries, PVC plastics, cigarettes also contain cadmium. Mercury is generated naturally in the environment from degassing of the earth's crust, from volcanic emissions. It exists in three forms: elemental mercury, organic and inorganic mercury. Mining operations, chloralkali plants and paper industries are significant producers of mercury (Goyer, 1996). It is also used in thermometers, thermostats and dental amalgam. Chromium is used in metal alloys and pigments for paints, cement, paper rubber and other materials. Copper normally occurs in drinking water from copper pipes, as well as from additives designed to control algal growth (file://C:\Documents and settings\Ebere\Desktop\ada\heavy-metals.htm). Agricultural and allied chemicals such as pesticides, fungicides, insecticides, commercial fertilizers and wood preservatives contain metals such as arsenic, manganese, lead and cadmium. Relevant occupational fields common in Nigeria such as steel making, foundry work, thermal cutting, welding, glass, ceramic production etc., and combustion of petrol with the additive methycyclopentadienyl manganese tricarbonyl (MMT), (an anti-knock agent in lead-free petrol) can release appreciable concentrations of manganese into the environment (Spiegel-ciobanu, 2006). In our recent study of heavy metals other than lead in flaked paints from one hundred and fifty buildings each of four major cities-Enugu, Onitsha, Aba and Port Harcourt in Eastern Nigeria, cadmium ranged from 9.032 ± 0.00 to 10.575 ± 0.000 and 6.845 ± 0.000 to 10.028 ± 0.002 (mg/kg) in Enugu and Onitsha, respectively. In Aba and Port Harcourt, the levels of cadmium ranged from 7.464 ± 0.002 – 9.343 ± 0.002 and 7.293 ± 0.002 – 9.395 ± 0.000 (mg/kg), respectively. Chromium levels in Enugu (0.940 ± 0.000 – 12.793 ± 0.002), Onitsha (1.613 ± 0.002 – 15.140 ± 0.000 mg/kg), Aba (15.206 ± 0.000 – 39.215 ± 0.000 mg/kg), Port Harcourt (33.118 ± 0.002 – 55.418 ± 0.002 mg/kg). Iron copper and zinc were significantly higher (Nduka et al., 2008), also of 168 building paint flakes from the four cities, 80% of them were found to have lead level higher than the US,EPA permissible level of 5mg/kg (Nduka et al., 2008). In their work, Maduabuchi and co-worker's (2006), established that 86% and 84% of the 50 beverages (canned and non-canned) in Nigerian markets failed to meet the US, EPA criteria for acceptable lead and cadmium levels in consumer products. 95.2% of the canned beverages and 75.8% of the non-canned beverages had iron levels exceeding the MCL.42% of the canned beverages and 82.7% of the non-canned beverages had manganese level above the MCL while 80.9% of the canned and 72.4% of the non-canned had nickel exceeding the MCL (Agbo, 2006). Cosmetics, lips and finger nail paint and other beauty care products sold in the Nigerian markets are known to contain heavy metals such as mercury (Okei, 2007). Soil samples, underground and surface water samples and food (agricultural product) samples collected in and around car battery manufacturing plants, cable manufacturing plant, petroleum products and vegetable oil manufacturing plant in Nnewi, south eastern Nigeria, were found to have very significant and trace concentrations of arsenic, lead cadmium, nickel, copper, iron, manganese, zinc and mercury (Orisakwe et al., 1999, 2004; Asomugha et al., 2005). Analysis of tannery wastewaters from six tanneries in three notable industrial estates of Kano State, Nigeria showed significant level of chromium, the concentration of chromium decreases with increase in distance from the point source (Hat et al., 2005). The chromium is discharged as waste from chrome, applied in the form of Basic Chromium Sulphate (BCS) to the hides and skins during processing (Awan et al., 2003). Some locally produced and imported infant formulae (both milk-based and soy-based types) sold in Nigerian markets

were found to contain copper, manganese, lead and zinc, although most of the metals are within tolerable limits (Olu-owolabi et al., 2005). Due to high cost of orthodox medicine and its non availability in some rural areas as well as doubts over its efficacy because of faking and adulteration, many Nigerians including the middle class has resorted to local herbal preparation for medication; this has been established as a source of heavy metal poisoning (Obi et al., 2006).

Waste Water/Sewage Irrigation

There is a gradual decline in fresh water availability for irrigation in most countries of the world especially the very industrialized countries. The resultant effect is the use of sewage and other industrial effluents for irrigating agricultural lands. Waste water irrigation, solid waste disposal, sludge application, vehicular exhaust, industrial activities, mining and processing of metal ore are significant source of heavy metals in agricultural fields. Although the concentration of heavy metals in sewage effluents are low, long-term use of these waste waters on agricultural lands often results in the building of the elevated levels of these metals in soils (Rattan et al., 2002). These have been documented in countries such as India and China (Rattan et al., 2009; Khan et al., 2008), such has not been documented in Nigeria but ample examples exist. In Nigeria local farmers use of poultry droppings and cow dung as rich source of organic manure and there is possible increase in phyto availability of biosolids – applied trace metals to plants have been raised on the assumption that decomposition of applied organic matter would increase phyto availability (Sukkariyah et al., 2005). In our previous study, we showed that refuse dumps can substantially increase the environmental heavy metal burden in Awka municipality, Nigeria. This is because organic and inorganic compounds that contain heavy metals are common at refuse dump sites in Awka, they degrade and decompose following favorable weather conditions thereby releasing various pollutants into soil and ground water (Nduka et al., 2006) and food crop planted in and around the dumpsites take up these metals (Nduka et al., 2008). In our evaluation and health risk assessment of vegetables and food crops on the bank of Agulu lake Nigeria, where peasant farmers irrigate their farmland with crude method, the results showed that soil and agricultural produce contained appreciable concentration of heavy metals that can compromise the health of consumers (yet to be published data). It is a known fact that short term crops such as vegetables are grown during dry season with waste water in Nigeria. Residential wastewater is a combination of excrete, flush water and all types of wastewater generated from household, also industrial wastewater such as textile and pharmaceutical effluents contains heavy metal (Nduka, 2012; Olaitan et al., 2013). Increasing and extensive use of pesticides, herbicides and fungicides releases heavy metal into the environment. Crops raised on the metal contaminated soils accumulate metals in quantities excessive enough to cause clinical problems both to animals and human beings from the heavy metal rich crops (Tiller, 1986). It could be concluded that long term wastewater irrigation has led to contamination of soils and food crops in within irrigated areas and heavy metals were shown a substantial buildup with a significant increase over reference soils.

DISTRIBUTION CHANNELS

Air

The harmathan dust of the N-E wind which carries various contaminants including heavy metals settles on building, trees, surface soils and other objects while some may be inhaled. Nriagu (1992a) reported high dust lead levels in Lagos metropolis. He further estimated that about 10 to 30% of the children in Africa might be suffering from lead poisoning. The rain from moisture laden S-W wind (Iloeje, 1981), dissolves and carries these metals into the soil and underground water by infiltration while others into surface water. Solid particles that accumulate on outdoor, impervious materials in urban environment are collectively referred to as “street dust.” The two main sources of street dust, with its trace element constituents are deposition of previously suspended particles (atmospheric aerosol) and displaced urban soil (Ferreira-Baptista and De-Miguel, 2005). Other sources include building deterioration, construction and renovation, corrosion of galvanized metal structures etc., contribute directly to the street – dust load within their proximity (Schwar et al., 1988; Hopke et al., 1980). Street dusts laden with metals are not deposited permanently; they are easily resuspended back into the atmospheric aerosol to which it contributes reasonable amount of trace element (Maxwell and Nelson, 1978).

Metals can be accumulated in topsoil from atmospheric deposition by sedimentation, impaction and interception implying that atmospheric pollution is one of the major sources of heavy metal contamination especially in urban area (Mingkui and Hao, 2009). Vehicular emission and street dust metal pollution within the urban centres emanates from varied sources via water transported material from surrounding soils, dry and wet atmospheric deposition, biological inputs, road surface wear, road paint degradation, particulate emissions and vehicular wear (Pruvot et al., 2006; Zhang et al., 2008; Duzgoren-Aydin, 2007; Abdul-Wahabi, 2004; Zhou et al., 2007).

Therefore monitoring of the metal content of dust samples is an efficient way to evaluate the environmental status of large area (Park et al., 2008; Wang et al., 2006). Open burning of built up refuse dumpsite and open-air incineration create hazards associated with environmental pollution including air particulates laden with metals. Nigeria as a developing country is faced with several construction activities such as roads, stadia, airports, bridges, buildings (hospitals, schools, offices and residential areas), all these contribute large tones of heavy metal laden dusts into the air. Mineral quarrying and mining also contribute large volumes of dust with metals into the air (Ivan and Mwatia, 2012). Industrial emission released from petrochemical plant and refinery, gas flares, bush burning can release smoke and ash with metal into the atmosphere.

Water

Street dust laden heavy metals deposited on surfaces are washed away by precipitation and it becomes an important component of the suspended and dissolved solid in street run-off and in receiving water bodies (Vermette et al., 1991). Metals accumulated in the environment can influence the ecosystem (Ahmed and Ishiga, 2006; Steiner et al., 2007; Lough et al.,

2005). The presence of heavy metals in road deposited sediments plays an important role in establishing storm water quality (Liu and Zhao, 2007; Gans et al., 2008; Murakami et al., 2008). When rain falls, heavy metals from both natural and anthropogenic sources are transported into receiving waters where they affect storm water runoff quality evidently. In several studies carried out on surface water, shallow well and bore-hole water samples in a bid to establish potable water quality of Niger Delta. It was established that most water samples were laden with heavy metals in concentrations for above international regulatory agency's permissible limit (Nduka and Orisakwe, 2007; Nduka and Orisakwe, 2009; Nduka and Orisakwe, 2011).

Figure 1. Map of Nigeria showing the two major rivers that empties into the Atlantic Ocean.

Surface and underground water and the atmosphere (air) are the major routes through which heavy metals are distributed in Nigeria. The country seems naturally structured for that (Figure 1). The River Niger rises from the Futa Jallon Mountain to the North-east of Sierra Leone, flows through other countries, and enters Nigeria from the west and runs South easterly to Lokoja where it forms a confluence with its main tributary –River Benue. Other main tributaries of the River Niger are the Sokoto, Kaduna and Anambra Rivers. The River Benue which has its source in the Cameroon Republic receives in its course the waters of rivers kastina-Ala and Gongola. All these with so many other rivers culminate into interwoven network of rivers, streams, lake, ditches and creeks of the Niger-Delta before emptying into the Atlantic Ocean. Underground water occurs in a discontinuous manner, though major sedimentary rock areas are more significant for ground water potential. The coastal areas, the Niger-Benue valleys, the Southeastern lowland, the Sokoto-Rima basin and the chad basin are remarkable for continuous aquifers. Borehole yield in the coastal plains is of the order of 40,914 liters/hour and in the alluvium, deposits of the Niger-Delta, is 55.006litres/hour (<http://www.nigerianembassy-chile.org/Nigerian/xgeography.shtml>). Acidic precipitation which has been reported in Nigeria (Nduka et al., 2008), can demobilize heavy

metals from the soil into the aquatic ecosystem where they bio-concentrate in lugworms, barnacles, algae, other planktonic and benthic organisms enroute to food webs. Since rivers are wide open to flooding which carry various contaminants including heavy metals, ecotoxicological study of the Niger-delta area of the River Niger starting from Onitsha (source), Ishukwa in Ndokwa-East Local Government Area of Delta State (Middle point) and Adai in Ndoni Local Government of River State (Tail point) showed that of all the metals – lead, cadmium, zinc and calcium analysed, for all the sampling sites were above USA, EPA Maximum Contaminant Level (MCL) (Orisakwe et al., 2001). For the fact that open and underground water bodies are regarded as final recipients of most environmental pollutants, in a study of pollution profiles of portable water supply in Warri Nigeria, surface and underground (shallow well and deep borehole) water had cadmium, chromium and lead in concentrations that are above USA EPA MCL (Nduka and Orisakwe, 2007). A study of quality integrity of dugwell and borehole water samples in Maiduguri, Borno State of Nigeria showed that more than 75% of all the water samples had lead, zinc, selenium, copper and iron above USA EPA MCL (Kolo and Bukar, 2005). The inter-connection of soil water, rain water, flood water, underground (shallow well and Borehole) water and surface water (the entire water cycle) help to re-distribute these heavy metals in the environment.

Man/Animal/Food Chain

Several domestic animals such as goat, sheep, cow etc., are reared in Nigeria by open grazing. Most dusts laden with metals settle on plant leaves in addition to the quantity taken up by plant root from soil. Grazing animals are directly affected by the consumption of forage and feed contaminated by airborne metal and somewhat indirectly by the up-take of metals through the roots (Udiba et al., 2013). Metal intoxication is one of the most frequent diseases in farm animals, particularly in those grazed on pasture. A number of reports have confirmed the transference of trace metals from contaminated soil to plants and from plants to livestock (Ali, 2010; Orisakwe et al., 1992).

The risk of metal poisoning through food chain increases as the soil metal level rises above the permissible concentration for a given metal (Udibe et al., 2013). This implies that grazing animals are more at risk as forage grasses are consumed directly without washing (which is the case in Nigeria). In the evaluation of metal accumulation in cattle raised in a serpentine- soil area, it was observed that tissue accumulation in animals showed resemblance to concentrations of some heavy metals in soils and forage- concentration of some heavy metals in animal tissues correlated positively with the heavy metal content in the soil (Nwude et al., 2010). Heavy metal transfer from soil to plant is dependent on many factors like soil properties, plant species and metal bio- availability for uptake in the soil- plant system (Makridis et al., 2012). Evidence exists that plant foliage may take up metals such as lead and these can be moved to other parts of plants. Some species of plants have the capacity to accumulate high concentrations of metals. The mobility and phyto availability of metals depend on their chemical nature. Most of the metals absorbed by plants on lands are retained in their roots (Udiba et al., 2013; Orisakwe and Co-workers, 2012) has reported high concentration of the metals in rice and cassava based meals in Nigeria. Another study performed in Nnewi, Nigeria found that the lead content in food and soil samples were also

found to be very high, that is 19mg/kg in fruits, 21mg/kg in cassava, and as high as 12, 102mg/kg in certain soil samples (Orisakwe et al., 2012; Orisakwe et al., 2004).

In a study to investigate the environmental impact of the refuse dump sites with a capture of the heavy metal levels in potable water and agricultural produce in Awka, Nigeria. It was established that a correlation exists between heavy metal levels of soil refuse dumpsites, agricultural produce, surface (stream) water and underground water (Nduka et al., 2008). In a study of heavy metal content of fish muscles of different fish species from Aladfa River, Warri Nigeria. It was established that the levels were above any internationally accepted standard (Nduka et al., 2010). Whereas in comparative study of different metal accumulating capacity of different fish organs (brain, gills, flesh and intestines) of different fish species, the result revealed that brain, gills and intestines accumulated more heavy metals than the muscles with minor variations (Nduka et al., 2007). Heavy metals can be transported, dispersed to and accumulated in plants and animals and can be passed across the food chains to humans (Hongyu et al., 2005; Ali, 2010).

Inhalation, accidental ingestion of contaminated soil, ingestion of contaminated water and absorption through the skin were also identified as the exposure route of these contaminants (Udiba et al., 2013). The fact that metal biomagnifying from one tropic level to another, animal higher in the food chain may accumulate more toxins than their food contains (Monteiro et al., 1996). This is the bane of man, the different route through which man accumulates heavy metals includes:

- Water – human
- Soil – human
- Air – human
- Plant – human
- Animal – human
- Air – animal – human
- Soil – plant – human
- Water – animal – human
- Soil – plant – animal – human
- Water – plant – animal – human

BIO-INDICATORS

Soil, water and biological species act as indicators of presence of heavy metals. Plant through tap root absorb metals dissolved in soil water, it is then eaten by animals or man. Some residual soil metals infiltrate into the underground water while others are leached into surface waters where they bio-concentrate in planktons, lugworms, barnacles, freshwater shrimps and other planktonic and benthic organisms enroute food webs. Simple and complex food web help to recycle these metals, therefore nutrition is an important exposure pathway to heavy metal toxicity. Various food items such as rice, potato, cassava, yams, okro, baobab leaves, melon seeds, spinach and locust beans sampled from markets in Kaduna, Kano, Niger and Abuja were analysed and found to contain appreciable concentrations of chromium, iron, cobalt and zinc, with little and limited amount of arsenic, cadmium, lead and mercury (Umar,

2004). Determination of trace elements in water lily and lettuce harvested from farmland along the banks of Angwan Rogo stream in Jos, Nigeria, showed an alarming concentrations of metals in the range (mg/kg): Fe (51.12 ± 0.35 - 59.01 ± 0.10), Cu (24.21 ± 0.71 - 28.12 ± 0.02), Zn (208.78 ± 0.01 - 252.00 ± 0.91), Pb (53.99 ± 0.86 - 68.06 ± 0.03) and Cd (8.31 ± 0.97 - 9.21 ± 0.01) for water lily while lettuce had the metals in the range of: Fe (57.78 ± 0.61 - 65.35 ± 1.3), Cu (18.21 ± 0.52 - 23.16 ± 0.86) Zn (301.70 ± 2.16 - 340.13 ± 0.04), Pb (62.13 ± 0.17 - 81.15 ± 1.08) and Cd (11.83 ± 1.12 - 12.71 ± 2.15), all the results in (mg/100g) (Salami and Non, 2002). Marine crabs, crustacean specimen, collected from different marine locations at Epe (Lagos State) and Warri (Delta State) had metals such as lead, zinc, copper, nickel, arsenic, mercury and cadmium in an amount above USA EPA MCL that may be detrimental to life (Okoye et al., 2002). Methyl mercury poisoning has been reported among people that depend on fish for their protein (Jemelov and Ramel, 1994). Metal bio-accumulation studies of *synodontis membranaceus* (catfish) and *Tilapia zili* (tilapia) from Anamabra River shows that the prevailing levels for the metals were Pb (61.32mg/kg), Fe (201.50mg/kg), Cu (5.13mg/kg), *synodontis membranaceus* showed high bio-accumulation factors of 350 and 219 for Mn and Pb respectively while tilapia showed 210 and 224 for Mn and Pb (Obodo, 2004). We have reported that fish parts such as gills, brain, liver, muscles and intestine of fish species from crude oil polluted water bio-accumulated Ni, Cr, Fe, Pb, Cd etc., differently (Nduka et al., 2006). Several studies have shown that plants have the ability to concentrate lead, leaf and root contain more lead than stem, and the contents of lead in different plant organs were positively correlated to the lead content in soil (Sridhar, 1988). Urine samples of occupational exposed artisans in Awka, Nigeria such as auto-mechanics, automobile riders and filling station fuel attendant had lead level in the range of 0.02-0.09 mg/l, urine been an excretory product, is an indication of high blood lead level among the subjects. (Nduka et al., 2008). Asogwa (1979) reported high blood lead levels among battery workers in Nigeria. Lead, cadmium, nickel and other industrial metals used as part of paint varnishes have been reported in liver and kidney amongst paint factory workers in Nigeria. An evaluation study on some toxicological effects of occupational exposure to paint, among 25 occupational exposed artisans and 25 students (control) was carried out in Nigeria, the results showed that, occupational exposure to cadmium, lead or nickel among paint factory workers, may compromise the liver and renal functions in man (Orisakwe et al., 2007).

PUBLIC HEALTH IMPLICATIONS OF HEAVY METAL POLLUTION IN NIGERIA

Chronic toxicity of heavy metals results from repeated or continuous exposures, leading to an accumulation in the body. Exposures may result from contaminated food, air, water or dust, living near hazardous waste site, and maternal transfer in the womb: Chronic exposure may occur in either the home or workplace. Symptoms of chronic toxicity may be similar to many common conditions and may not be readily recognized (Anon, 1993; Ferner, 2001). Exposure to arsenic occurs mostly in the workplace, near hazardous waste sites, or in areas with high natural levels. Symptoms of acute arsenic poisoning are sore throat from breathing, red skin at contact point or severe abdominal pain, vomiting and diarrhea. Cardiovascular changes in early stage, neuropathy (Inflammation and wasting of the nerves) occurs over

several years. Excessive darkening of the skin (hyperclose pigmentation) in areas not exposed to sunlight, excessive formation of skin on the palms and soles (hyperkeratosis), or white bands of arsenic deposits across beds of the fingernails as well as birth defects, liver injury and malignancy. Ayoola (1979) reported on ten (10) cases of lead (Pb) poisoning. He drew attention to the difficulty of the diagnosis of Pb toxicity and cautioned that with the rapid industrialization of Nigeria, doctors and other health workers should be aware of the possible increase in the incidence of plumbism. Ayoola (1979) also noted the long term consequences of Pb even after quitting a Pb-based occupation. The levels of black carbon and tetraethyl lead (TEL) were measured in the tear film of 100 children selected by a simple random technique from each industrial location-children attending eye clinics in Delta State government hospital located at Warri, Ekpan and Aladja, were used, persistent itching, foreign sensation and specified areas of conjunctival/limbal discoloration were used as markers for pollution keratoconjunctivitis (PKC). Biochemical assays showed that tears samples contained some levels of TEL among the sample population. This is ascribed to rapid urbanization and industrialization occasioned by pollutants from drilling, production and refining of crude oil and production of petrochemicals (Asonye and Bello, 2004). Lead exposures acts synergistically with iron deficiency and sickle cell traits as low dose inocula which can attenuate plasmodia blood-stage infections. This leads to the suggestion that a reduction in the level of some environmental exposures may interfere with the natural acquisition of immunity to malaria. Lead poisoning is the 6th most important contributor to the global burden of diseases measured in disability adjusted life years (DALYs), with sub-saharan African countries being predominantly responsible for the global DALYs (Pruss-Ustun and Corvalan, 2006). Recent studies confirm that lead protect against parasitemia in individuals (Nriagu et al., 2007) as well as in plasmodium-infected mice (Kempe et al., 2005; Koka et al., 2007). High intra-erythrocyte concentration of lead can also affect several essential cellular processes adversely, such as inhibition of protein synthesis (Graziano et al., 1991). It has high affinity for the side chains of many proteins such as tranferrin (Qian et al., 1997), Mucin (Conrad et al., 1991), mobilferrin-divalent metal; ion tranporter, DMTI (Gunshin et al., 1997), hemoglobin (Bartrop and smith, 1972) and enzymes of heme synthesis (Goldberg, 1972). The ability of Pb^{2+} to undergo metathesis reaction with Zn^{2+} and Ca^{2+} metalloproteins resulting in loss of metabolic function continues to be a primary hypothesis underlying the detrimental effects of lead exposure (Lewis and Cohen, 2004). Several studies have shown that lead can cause adverse effects on various organ and systems in all species under experimental conditions, including the blood, reproductive, immune system and kidneys (WHO, 1995). Lead is a highly neurotoxic agent that particularly affects the developing CNS and also interferes with excitatory neurotransmission by glutamate, which is the transmitter at more than half the synapses in the brain and is critical for learning (Cory-Slechta, 1995). Manganese is best characterized as neurotoxin, occupational exposures are associated with characteristic syndrome called manganism which involves both psychiatric symptoms and parkinsonism features (Dobson et al., 2004). Exposures through drinking water has been associated with sub clinical neurologic effects in Greek adults (Kondakis et al., 1989). Toxicological studies have suggested that copper, manganese and lead can reduce testosterone production in, in vitro and in vivo (Zeng et al., 2013). Although copper and manganese are essential for good health (Meeker et al., 2008; Kendall et al., 2000), relatively high levels of exposure to these essential metals may result in adverse male reproductive health for example, exposure to manganese at high doses has been found to decrease

testicular weight and semen quality in rat and mice (Laskey et al., 1982). Excessive human exposure to copper and manganese in blood has also been associated with decreased semen quality (Meeker et al., 2008). Manganese is a potent toxin with a myriad of neural deficit ranging from learning disabilities (Henn et al., 2011), manganism and manganese-induced Parkinsonism (Aschner et al., 2009; Sahnib et al., 2007), compulsive behaviors, emotional lability, hallucinations and attention disorders (Solis-Vivanco et al., 2009). High maternal manganese levels are associated with low fetal birth weight (Zotal et al., 2009) and increased infant mortality (Spangler and Spangler, 2009). Copper is also an essential trace element, its absorption occurs through the lungs, skin and gastro-intestinal tract (US EPA, 1985). Individuals with copper toxicity shows an abnormally high levels of copper in the liver, kidneys, brain, eyes and bones (ATSDR, 1990). Copper has been implicated in early childhood liver cirrhosis (ECLC) regarded as non-indian childhood cirrhosis (NICC). High copper levels in the body may pose a risk in reduction of total homo-cysteine and folate which are essential to body metabolism (Tamura and Turnlund, 2004). Though, iron is regarded as non toxic since it is contained in most blood supplement and food, hence a blood builder. Biologically, iron is the most important transition element. The human body contains about 4g of iron out which about 70% is found in hemoglobin, the red pigment in erythrocytes. Most of the iron is stored in the body as ferretin (Lee, 1996). Although iron performs a number of bio-inorganic functions in living things, such as oxygen storage in muscles tissue (myoglobin), electron transfer in plant and bacteria (ferredoxins) and electron carrier in plants, animals and bacteria (cytochrome), etc. (Lee, 1996). Excessive intake of iron can cause a disorder which leads to serious health problems or premature death (Oliver and Brittenham, 1997). Iron toxicity may damage the liver, heart and endocrine glands, leading to debilitating and life threatening problems such as diabetes, heart failure and poor growth (Andrews, 1999; Porter, 2001). Cadmium concentrates along the food chain and ultimately accumulates in the body of people eating contaminated food. It is present in tobacco smoke and further contributing to human exposure. Cadmium is highly toxic, accumulating in the body and eventually causing effects as tubular dysfunction, disturbances in calcium homeostatis and metabolism (WHO, 1992). It is capable of inducing renal, hepatic and testicular injury (Suzuki et al., 1989). Although cases of over cadmium nephropathy was described in the context of high occupational or environmental exposures, some studies has suggested that cadmium at low environmental exposures and as currently found in industrialized countries can cause subtle renal effects leading to modest increase in the urinary excretion of micropoteins (Buchet et al., 1990; Jarup et al., 2000; Barbure et al., 2006; Akesson et al., 2005). Cadmium and several cadmium containing compounds are carcinogens and can induce many types of cancer. It is estimated that about 10% of the cadmium content of a cigarette is inhaled through smoking, therefore absorption of cadmium from the lungs is much more effective than that from the gut and as much as 50% of the cadmium inhaled via cigarette smoke may be absorbed (Friberg, 1983). Previously, the International Agency on Cancer Research (IARC) has classified cadmium as a human carcinogen (group 1) on the basis of sufficient evidence in both humans and experimental animals (IARC, 1993). Cadmium (Cd^{2+}) because of its size and charge similarity can substitute for calcium (Ca^{2+}) and included in bones with its attendant toxic effect on the bones.

Occupational exposure to chromium mainly occurs by inhalation, but it may involve the gastro intestinal tract and skin (De flora, 2000), this means that the respiratory tract is the

primary target organ for Cr (VI) compounds. Improved work ethics, procedures and hygiene measures have reduced occupational exposure to Cr (VI) compounds but long-term Cr (VI) exposure may still cause human health problems.

Long term exposure to chromium can cause kidney, liver and nerve tissue damage. Chronic exposure leads to ulcerations and perforations of the nasal septum, chronic bronchitis, decreased pulmonary function, pneumonia and other respiratory effects (Bradshaw et al., 1998). Acute exposure may cause shortness of breath, coughing and wheezing (Sobaszek et al., 2000).

Most chromium compounds are carcinogenic, long exposure may cause kidney, liver and nerve tissue damage (Praydot, 1999). Although the mechanism of Cr(VI) cytotoxicity is not completely understood, several studies have shown that its compounds induce oxidative stress, DNA damage, apoptotic cell death and altered gene expression (Bagchi et al., 2002; Zhitkovich, 2005). Unstable intermediates such as Cr(IV) or Cr(V) can be formed by redox-active enzymes and small molecules which mediate the formation of free hydroxyl, thiyl, ascorbate and carbon-based radicals (Ding and Shi, 2002; Levina and Lay, 2005), these are capable of damaging macromolecular targets such as DNA (Stohs et al., 2001).

The carcinogenic properties of chromium (VI) have been known for a long time (Barceloux, 1999). The acute toxicity of chromium (VI) is due to its strong oxidational properties, when it reaches the blood stream; it damages the kidneys, liver and blood cells through oxidation reactions. Hemolysis, renal and liver failure are the results of these damages (Dayan and Paine, 2001). Human exposure to nickel causes a variety of pathologic effects but adverse health effects depend on the route of exposure (inhalation, oral or dermal) and can be classified according to systemic, immunologic, neurologic, reproductive, developmental, or carcinogenic effects following acute (01 day), subchronic (10 – 100days), and chronic (100days or more) exposure periods (Das et al., 2008).

Pharmacokinetic studies in humans indicate that nickel is absorbed through the lungs (Bernnett, 1984; Sunderman and Oskarsson, 1991), gastrointestinal tract (Patriarca et al., 1997; Sunderman Jr, 1989) and Skin (Fullerton et al., 1986), following absorption from the lungs and the gastrointestinal tract, nickel is excreted in the urine (Bernacki et al., 1978, Angerer and Lehnert, 1990). Major accumulation of nickel in the body occurs in the kidney and inflammation in the bronchioles, alveolar congestion, alveolar cell hyperplasia and congestion in the lumen do occur (Gupta et al., 2006). Some major clinical effects of mercury and arsenic include tremor, gingivostomatitis, peripheral neuropathy, acrodynia, acute tubular necrosis, gastroenteritis, CNS effects and birth effects (Das et al., 2011). Despite the awareness of health hazards associated with organic and inorganic chemical compounds as well as heavy metal exposures, medical diagnosis of patients who may be suffering from heavy metal poisoning are highly reported in Nigeria hospitals. Although serious evidence that non communicable diseases (NCDs) such as cardiovascular diseases, diabetes mellitus, cancer and respiratory diseases which may be associated with heavy metal exposures and which were, before now, the major causes of morbidity and mortality in the developed world are now emerging as an important component of the disease burden in developing countries like Nigeria (Gill, 1999). In their work, Unachukwu et al., (2008), showed that out of 3294 total medical admissions at the University of Port-Harcourt Teaching Hospital (UPTH) Nigeria, from June, 2000 to June, 2004, 56.2% (1853) were cases of various non-communicable diseases. The breakdown showed that diseases of the cardiovascular, endocrine and renal systems occurred most accounting for 35.7% (662), 18.5% (342), and

18.6% (311) respectively. Others were neurological 14.5% (269), gastrointestinal 5.0% (93), haematological 4.9% (911), respiratory problems 2.4% (44), musculoskeletal 1.82% (33) while dermatological diseases accounted for 0.4% (7) of non-communicable admissions (Unachukwu et al., 2008), hypertension, diabetes mellitus and chronic renal failure were the most common cardiovascular, endocrine and renal disorders respectively but most Nigerian medical personnel, during diagnosis do not look on the direction of heavy metals as possible causes of these non communicable diseases .Various heavy metals have been implicated in most of these non-communicable diseases. Some major clinical effects of mercury and arsenic include tremor, gingivostomatitis, peripheral neuropathy, acrodynia, acute tubular necrosis, gastroenteritis, CNS effects and birth effects (Das et al., 2011). Various heavy metals have been implicated in most of these non-communicable diseases. Several studies suggest that the presence of lead and cadmium in the reproductive tract of the men attending infertility clinics may be related to a moderate alteration of their seminal parameters (Mendiola et al., 2011). In his well reported work, Giwa-Osagie (2003) revealed that Nigeria has 12 million infertile persons, which was originally believed to be caused by infection (Cates et al., 1985) but majority of the cases remained after treating infection. Amongst African adult couples, it is estimated that 10-25% are subfertile and of the subfertile couples, female factors accounted for about 55% and male factors about 30-40% while 5-15% are unexplained causes (Giwa-Osagie, 2011). A study carried out in Port Harcourt south-south Nigeria on the prevalence hypertension by Onwuchekwa and Asekomeh (2009) correlated with that of Adedoyin and Adesoye (2005), Onwuchekwa and Asekomeh (2009) work showed that congestive cardiac failure implicated hypertension (56.3%) as the major cause while other cardiomyopathy, chronic renal failure, rheumatic heart disease and ischemic heart disease accounted for 12.3%, 7.8%, 4.3% and 0.2%, that of Adedoyin and Adesoye (2005), showed hypertension (32%), stroke (17.4%), cardiomyopathies (7.6%) while other cardiovascular diseases accounted for (5.6%). Clinical profile of hypertension in Port Harcourt reviewed by Onwuchekwa and Chinenye (2010) showed that 28.2% of all the medical admissions were due to hypertension with its attendant complications such as stroke (39.9%), heart failure (22%), and renal failure (9.4%). Mortality rate caused by stroke (51.5%), heart failure (14.1%) and renal failure (12.1%) follows the same sequence. Most Nigerian adults (about 20-25%) are regarded as being hypertensive (Ogah, 2006). In study carried out in Abeokuta, south western Nigeria, hypertension (56.7%) was the major cause of cardiovascular ailment, rheumatic heart disease (3.7%) and cardiomyopathy (3.0%) while other CVDs accounted for 4.4% (Ogah et al., 2008), These studies correlating that of Unachukwu et al., (2008), shows that non communicable diseases are a major cause of death in Nigeria. Previously the battle with communicable diseases, hygiene and other third world health challenges ignored health hazards posed by environmental heavy metals. Environmental contamination and exposure to heavy metals is on the rise in Nigeria and their excessive dietary intake are linked with cancers of stomach, small intestine, large intestine, ovary, kidney, lungs, myeloma, all leukemia and all lymphomas (Reddy et al., 2004). These fact are complicated the very facts that human biological half-lives for heavy metals are variably long, example the half-life for cadmium in the kidney is decades, other heavy metals can readily pass across the placenta, found in the breast milk and exert very detrimental effect on the behavior, intellect and developing nervous system in children (Sanders et al., 2009) In all most heavy metal accumulation have been associated with shortening of life expectancy, progressively steady decline in energy, productivity quality of life to accelerated CVDs,

premature, dementia and total debilitation (Orisakwe, 2014) and a total increase in family health problems, reduced joy and happiness and medical expenses. In the aftermath of Lead poisoning in Zamfara State, Nigeria, particularly in Anka and Bukkuyum Local Government Area of the State, Subsequent investigations by the centers for Disease Control, the World Health Organization (WHO) and Zamfara State Ministry of Health confirmed that hundreds of children below five years were at risk of death or serious acute and chronic health effects due to high levels of lead and mercury (WHO, 2011).

CONCLUSION

We conclude that greater Nigerian environment is increasingly contaminated with heavy metals, and that the populace including children, and occupationally exposed artisans is environmentally exposed to these heavy metal contaminations through various means such as air, water and food and that human health problems associated with heavy metal exposure other than communicable diseases are on the increase and should be declared public health emergency by Nigerian policy makers.

Chapter 505

**TESTIMONY OF DR. KATHRYN M. WELLS, MEDICAL
DIRECTOR, DENVER HEALTH CLINIC AT THE FAMILY
CRISIS CENTER. HEARING ON “IS THE DEPARTMENT
OF JUSTICE ADEQUATELY PROTECTING THE PUBLIC
FROM THE IMPACT OF STATE RECREATIONAL
MARIJUANA LEGALIZATION?”***

Chairman Grassley, Co-Chairman Feinstein, distinguished members of the Caucus and guests: Thank you for providing me with the opportunity to appear before you today to discuss my perspective of the impact legalization of recreational marijuana has had on Colorado’s children and the child welfare system. As a Child Abuse Pediatrician and someone who has observed and studied the impact of substance abuse on children and child maltreatment for almost 20 years, I am hoping that my experiences related to marijuana legalization in Colorado might help inform your decisions regarding the role of the Department of Justice in assisting states in measuring, understanding and mitigating its impact on children. In Colorado, we have come to understand that these are extremely complex issues that seem to generate many more questions than answers. In the next few minutes, I will speak to the impact such policies have on children as informed by my experience in Colorado.

Most of my comments can be viewed through the Department of Justice’s marijuana enforcement priority of preventing the distribution of marijuana to minors. Regardless of one’s overall position on marijuana legalization, I trust most would accept this priority. However, child health and welfare in Colorado has been endangered for many reasons but largely because of the skyrocketing access to and subsequent use of marijuana edible products. Although there are many complex issues, I will use my time this morning to share my experiences and observations on three issues:

* This is an edited, reformatted and augmented version of testimony presented April 5, 2016 before the Senate Caucus on International Narcotics Control.

- Marijuana edibles;
- Additional issues related to child safety and welfare, and
- The impacts of the use of marijuana during pregnancy and breastfeeding.

MARIJUANA EDIBLES

Marijuana infused products such as candy, brownies and cookies are all inherently appealing to children. Because of this appeal, better regulations around edibles is essential to prevent child ingestion. A systematic literature review of unintentional marijuana exposures in children undertaken by Colorado's Retail Marijuana Public Health Advisory Committee found substantial evidence that more unintentional marijuana exposures of children occur in states with increased legal access to marijuana, and that such exposures can lead to significant clinical effects requiring medical attention.^{1, 2,3} Additionally, they found moderate evidence that the use of child-resistant packaging reduces unintentional pediatric poisonings in general, while there is little data specifically related to marijuana.^{4,5,6}

Indeed, review of Colorado data over the past decade has revealed a very concerning trend. According to data compiled by the Rocky Mountain Poison and Drug Center, the number of marijuana-related exposures in children ages 0 to 5 increased from an average of 4 per year during the pre-commercialization years of 2006-2008, to 13 per year during post-commercialization from 2009-2012, a 225% increase, to an average of 31 per year following legalization in 2013 and 2014, a subsequent 138% increase. In this same time period (2013-2014), the average percentage of all marijuana-related exposures occurring in children ages 0 to 5 in Colorado was 17.71%, far exceeding the national average of 5.95%.

Because of the increased potency of these exposures, children are often requiring more medical interventions when they present after an ingestion. According to Colorado Hospital Association data demonstrated that the rates of hospitalizations and emergency department visits in children up to 9 years of age due to possible marijuana exposures increased more than five-fold between the period from 2001- 2009 to 2010-2013. In addition to the clear health concerns, child ingestions prompt reports to child welfare and sometimes law enforcement posing additional challenges to systems that then attempt to determine the source and nature of the exposure, whether it was intentional or accidental, and the potential for future risk.

While Colorado has worked hard to address this issue with regulations that will be implemented October 2016 determining packaging guidelines for both recreational and medicinal marijuana and serving/dosage size related to recreational marijuana, it is important to note that the best packaging only protects children up to the age of 5 years.

ADDITIONAL ISSUES RELATED TO CHILD SAFETY AND CHILD WELFARE

Beyond access to edibles, Colorado has experienced several other challenges related to the impact of the legalization of marijuana on children that we are trying to understand more

completely but are hindered by the lack of data. For example, home cultivation of marijuana including home grows and processing of edibles has raised questions as to the risk to children. While we have now restricted the ability to legally extract THC utilizing butane due to the risk of explosions, other risks and mandates to report to child welfare are less clear. In general, concerns of child neglect arise when cultivation does not meet current Colorado legal standards. Electrical hazards, improper ventilation or access to pesticides or unrestricted access to marijuana itself due to improper storage are all valid concerns.

Another issue we have seen is an impact on our schools. The *Denver Post* examined marijuana store locations and found 25 marijuana stores closer than 1,000 feet to at least one nearby school.⁷ And using data compiled by PBS in Colorado, there are signs that more students are using marijuana and that this is an increasing problem for teachers, counselors, and other school personnel.⁸

Another challenge is the ability to determine if someone is impaired while operating a vehicle or parenting, whether the use is recreational or medicinal. Impairment is an important issue in determining if a caregiver is safe to care for a child, a decision that challenges child welfare workers daily. Generally, impaired parenting is defined as the inability of a caregiver to create, maintain, or regain an environment that promotes optimum growth and development of a child, a standard that is often challenging to determine in issues related to the use of marijuana. Due to the lipophilic (or fat-loving) nature of the drug and its storage in the human body in fats, standard testing levels of intoxication and impairment are much more difficult to determine than with other substances of abuse such as alcohol, prescription or illicit drugs.

Finally, another unanticipated area of concern is the issue of parental administration of cannabinoids for medicinal purposes in children without proper authorization. As you are aware, many families with children who are suffering life threatening disease processes such as intractable seizures have flocked to Colorado for the promise of the potential therapeutic benefit of cannabinoids such as cannabidiol (CBD) oil. In order to legally administer this drug to a child, parents are required to obtain special permission, a process requiring a recommendation of two physicians licensed to practice medicine in Colorado. This process takes time and while awaiting this, many parents obtain and administer the product without a recommendation, placing healthcare providers in a difficult dilemma, ignore potentially vital information related to current therapeutic interventions that may negatively interact or compromise their proposed medical management or risk family trust by following their legal mandate by reporting such information to child welfare.

PREGNANCY AND BREASTFEEDING

Another topic I wish to touch on briefly is the use of marijuana use during pregnancy and breastfeeding. The legalization of recreational marijuana has underscored the need to better understand the impact of exposure on the unborn fetus as well as the breastfeeding infant to the different forms of marijuana. The potential for adverse outcomes in exposed offspring of marijuana-using mothers prompted Colorado's Retail Marijuana Public Health Advisory Committee to review the available literature on physical, developmental and mental health outcomes of marijuana exposure during pregnancy and breastfeeding. While it is important to

note that this literature is based on smoked marijuana alone as well as much lower potency THC than is being used currently, the Committee found moderate evidence that maternal use of marijuana during pregnancy is associated with negative effects on exposed offspring, including cognitive function, IQ and attention.^{9,10,11,12 13,14,15,16} Importantly, these effects may not appear until adolescence.

Additionally, the Committee reviewed the very limited research related to breastfeeding and marijuana and found that biological evidence shows that THC is present in the breast milk of women who use marijuana and that infants who drink breast milk containing THC absorb and metabolize the THC.¹⁷ However, only mixed evidence was found for whether or not an association exists between maternal use of marijuana while breastfeeding and motor development in exposed infants.^{18,19}

The issue of prenatal exposure to marijuana has been especially challenging because in Colorado, an infant born positive for a Schedule I drug or a Schedule II drug not being used by the mother as prescribed is defined as a case of child abuse. Therefore, if an infant is born positive for THC in Colorado, under current law, this meets the healthcare provider's mandate to report the case to child welfare and can be used as evidence of child abuse in civil court. Many healthcare providers have found this new reality ethically challenging. Women who deliver an infant positive for THC, not realizing it was grounds for a child welfare action, may now be faced with child welfare involvement that may include removal of their infant and/or ongoing monitoring. Additionally, healthcare professionals, child welfare workers, and judges are often met with the challenging task of determining when and if a mother can safely breastfeed her child.

Due to these many challenges, the Committee identified many areas in need of research that may impact public health policies and prevention strategies such as the adverse health effects and marijuana use and breastfeeding including the effects of cannabidiol (CBD) and other cannabinoid use, the consumption of edibles or by vaping and the impact of potency of THC consumed. Further, research is needed to determine the length of time THC remains in breast milk, the comparison of amount of THC in breast milk to maternal blood or urine THC levels.

CONCLUSION

Due to the many challenges faced by Colorado's child-serving professionals, the Colorado School of Public Health has undertaken a Health Impact Assessment as a systematic process in which evidence based/informed recommendations are developed to be responsive to community and stakeholder input in a local policy context. This effort was largely initiated due to perceived inconsistencies in how marijuana use and exposures were operationalized in child welfare in an effort to define greater consistency and develop evidence based/informed recommendations. This challenging work continues specifically related to issues related to mandatory reporting, child welfare screening and assessment and the management of open child welfare cases where marijuana is a factor. This process has also combined with ongoing efforts to better define situations related to substance use and children, including child welfare, in the Colorado Children's Code where House Bill 16-1386 was just introduced and set for hearing next week.

I urge the Federal government and other states contemplating similar legal changes involving the legalization of recreational marijuana to take the time to consider the impact of such policy on the health and wellbeing of our youngest citizens. We desperately need funding support and laws that allow research needed to inform these critical policies and regulations that impact the health, welfare and safety of our most vulnerable but critical resource, our children.

Chapter 506

PUBLIC HEALTH SERVICE AGENCIES: OVERVIEW AND FUNDING (FY2015-FY2017)*

***C. Stephen Redhead, Agata Dabrowska, Erin Bagalman,
Elayne J. Heisler, Judith A. Johnson, Sarah A. Lister
and Amanda K. Sarata***

SUMMARY

Within the Department of Health and Human Services (HHS), eight agencies are designated components of the U.S. Public Health Service (PHS). The PHS agencies are funded primarily with annual discretionary appropriations. They also receive significant amounts of funding from other sources including mandatory funds from the Affordable Care Act (ACA), user fees, and third-party reimbursements (collections).

- The *Agency for Healthcare Research and Quality (AHRQ)* funds research on improving the quality and delivery of health care. For several years prior to FY2015, AHRQ did not receive its own annual appropriation. Instead, it relied on redistributed (“set-aside”) discretionary funds from other PHS agencies for most of its funding, with supplemental amounts from the ACA’s mandatory Patient-Centered Outcomes Research Trust Fund (PCORTF). In FY2015 and FY2016, AHRQ received its own discretionary appropriation in lieu of set-aside funds, with the FY2016 level of \$428 million below the FY2015 level of \$443 million.
- The *Centers for Disease Control and Prevention (CDC)* is the federal government’s lead public health agency. CDC obtains its funding from multiple sources besides discretionary appropriations. The agency’s funding level has fluctuated in the past few years, with the FY2016 level of \$11.8 billion above the FY2015 level of \$11.2 billion. The *Agency for Toxic Substances and Disease Registry (ATSDR)* investigates

* This is an edited, reformatted and augmented version of a Congressional Research Service, Publication No. R44505, dated May 19, 2016.

the public health impact of exposure to hazardous substances. ATSDR is headed by the CDC director and included in the discussion of CDC in this report.

- The *Food and Drug Administration (FDA)* regulates drugs, medical devices, food, and tobacco products, among other consumer products. The agency is funded with annual discretionary appropriations and industry user fees. The FDA's funding level in FY2016 was \$4.7 billion—above the FY2015 level of \$4.5 billion—with user fees accounting for about 43% of FDA's total funding.
- The *Health Resources and Services Administration (HRSA)* funds programs and systems that provide health care services to the uninsured and medically underserved. HRSA, like CDC, relies on funding from several different sources. The agency's funding increased from \$10.6 billion in FY2015 to \$10.8 billion in FY2016.
- The *Indian Health Service (IHS)* supports a health care delivery system for Native Americans. IHS's funding, which includes discretionary appropriations and collections from third-party payers of health care, increased between FY2015 and FY2016 from \$5.9 billion to \$6.2 billion. Appropriations and collections both increased during that period.
- The *National Institutes of Health (NIH)* funds basic, clinical, and translational biomedical and behavioral research. NIH gets more than 99% of its funding from discretionary appropriations. Recent increases in NIH's annual appropriations have boosted its funding level to a new high of \$32.3 billion in FY2016, compared to \$30.3 billion in FY2015.
- The *Substance Abuse and Mental Health Services Administration (SAMHSA)* funds mental health and substance abuse prevention and treatment services. SAMHSA's funding, about 95% of which comes from discretionary appropriations, was approximately \$3.6 billion in FY2015 and \$3.7 billion in FY2016.

INTRODUCTION TO THE PHS AGENCIES

The Department of Health and Human Services (HHS) has designated eight of its 11 operating divisions (agencies) as components of the U.S. Public Health Service (PHS). The PHS agencies are: (1) the Agency for Healthcare Research and Quality (AHRQ), (2) the Agency for Toxic Substances and Disease Registry (ATSDR), (3) the Centers for Disease Control and Prevention (CDC), (4) the Food and Drug Administration (FDA), (5) the Health Resources and Services Administration (HRSA), (6) the Indian Health Service (IHS), (7) the National Institutes of Health (NIH), and (8) the Substance Abuse and Mental Health Services Administration (SAMHSA).¹

While the PHS agencies all provide and support essential public health services, their specific missions vary. With the exception of FDA, the agencies have limited regulatory responsibilities. Two of them—NIH and AHRQ—are primarily research agencies. NIH conducts and supports basic, clinical, and translational medical research. AHRQ conducts and supports research on the quality and effectiveness of health care services and systems.

Three of the agencies—IHS, HRSA, and SAMHSA—provide health care services or help support systems that deliver such services. IHS supports a health care delivery system for American Indians and Alaska Natives. Health services are provided directly by the IHS, as

well as through tribally contracted and operated health programs, and through services purchased from private providers. HRSA funds programs and systems to improve access to health care among low-income populations, pregnant women and children, persons living with HIV/AIDS, rural and frontier populations, and others who are medically underserved. SAMHSA funds community-based mental health and substance abuse prevention and treatment services.

CDC is a public health agency that develops and supports community-based and population-wide programs and systems to promote quality of life and prevent the leading causes of disease, injury, disability, and death. ATSDR, which is headed by the CDC director and included in the discussion of CDC in this report, is tasked with identifying potential public health effects from exposure to hazardous substances. Finally, FDA is primarily a regulatory agency, whose mission is to ensure the safety of foods, dietary supplements, and cosmetics, and the safety and effectiveness of drugs, vaccines, medical devices, and other health products. In 2009, Congress gave FDA the authority to regulate the manufacture, marketing, and distribution of tobacco products in order to protect public health.

The programs and activities of five of the PHS agencies—AHRQ, CDC, HRSA, NIH, and SAMHSA—are mostly authorized under the Public Health Service Act (PHSA).² While some of FDA's regulatory activities are also authorized under the PHSA, the agency and its programs derive most of their statutory authority from the Federal Food, Drug, and Cosmetic Act (FFDCA).³ HRSA's maternal and child health programs are authorized by the Social Security Act (SSA),⁴ and many of the IHS programs and services are authorized by the Indian Health Care Improvement Act.⁵ ATSDR was created by the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA, the "Superfund" law).⁶

SOURCES OF PHS AGENCY FUNDING

The primary source of funding for each PHS agency is the discretionary budget authority it receives through the annual appropriations process.⁷ AHRQ, CDC, HRSA, NIH, and SAMHSA are funded by the Departments of Labor, Health and Human Services, and Education, and Related Agencies (LHHS) appropriations act. Funding for ATSDR and IHS is provided by the Department of the Interior, Environment, and Related Agencies (Interior/Environment) appropriations act. FDA gets its funding through the Agriculture, Rural Development, Food and Drug Administration, and Related Agencies (Agriculture) appropriations act.⁸

Secretary's Transfer Authority

The annual LHHS appropriations act gives the HHS Secretary limited authority to transfer funds from one budget account to another within the department. The Secretary may transfer up to 1% of the funds in any given account. However, a recipient account may not be increased by more than 3%. Congressional appropriators must be notified in advance of any transfer.⁹

The HHS Secretary used this transfer authority in FY2013 and again in FY2014 as part of a broader effort to provide the Centers for Medicare & Medicaid Services (CMS) with additional funding to implement the Affordable Care Act (ACA).¹⁰ In FY2013, for example, NIH was the primary source of transfers both to CMS for ACA implementation and to CDC and SAMHSA to help offset a loss of funding for those two agencies from the ACA's Prevention and Public Health Fund (PPHF, discussed below). A significant portion of the FY2013 PPHF funds that were originally allocated to CDC and SAMHSA were reallocated to CMS, also for ACA implementation. In FY2014, NIH was again the primary source of transfers to CMS to support ACA implementation.¹¹

PHS Evaluation Set-Aside

In addition to the transfer authority provided in the annual LHHS appropriations act, Section 241 of the PHSA authorizes the HHS Secretary, with the approval of congressional appropriators, to use a portion of the funds appropriated for programs authorized by the PHSA to evaluate their implementation and effectiveness.¹² This longstanding budgeting authority is known as the Public Health Service Evaluation Set-Aside (set-aside), or PHS budget "tap."

Under this authority the appropriations of numerous HHS programs are subject to an assessment. Although the PHSA limits the set-aside to no more than 1% of program appropriations, in recent years the annual LHHS appropriations act has specified a higher amount. The FY2016 LHHS appropriations act capped the set-aside at 2.5%, the same percentage that has been in place since FY2010.¹³

Following passage of the annual LHHS appropriations act, the HHS Budget Office calculates the assessment on each of the donor agencies and offices. These funds are then transferred to various recipient agencies and offices within the department for evaluation and other specified purposes, based on the amounts specified in the appropriations act.¹⁴

Table 1 shows the total assessments and transfers for FY2013, by HHS agency and office, and indicates whether the entity was a net donor or recipient of set-aside funds that year. These figures are broadly representative of the distribution of set-aside funds that occurred each fiscal year over a period of several years prior to FY2015, when the appropriators decided to make major changes to the allocation of such funds.

NIH, whose annual discretionary appropriation exceeds that of all the other PHS agencies combined, is subject to the largest assessment of set-aside funds. NIH contributed almost \$710 million (69%) of the \$1.026 billion in set-aside funds in FY2013. However, the agency received \$8 million in set-aside funding, making it a significant net donor of set-aside funds. Similarly, HRSA contributed more set-aside funds than it received in FY2013. On the other hand, AHRQ, CDC, and SAMHSA were net recipients of set-aside funding in FY2013. The Administration for Children and Families (ACF) and various offices within the Office of the Secretary (OS) also received set-aside funds.

Table 1. PHS evaluation set-aside fund assessments and transfers
dollars in thousands

	FY2013			FY2016		
Agency/ Office	Total Assessments	Total Transfers	Net Gain (Loss)	Total Assessments	Total Transfers	Net Gain (Loss)
NIH	709,536	8,200	(701,336)	733,198	780,000	46,802
HRSA	126,340	25,000	(101,340)	209,399	—	(209,399)
CDC	116,170	375,048	258,878	156,003	—	(156,003)
SAMHSA	53,867	129,667	75,800	29,661	133,667	104,006
AHRQ	78	365,362	365,284	6,555	—	(6,555)
CMS	—	—	—	—	184,000	184,000

ACL	158	—	(158)	898	—	(898)
OS	19,412	116,522	97,110	29,281	67,328	38,047
Total	1,025,561	1,025,561		1,164,995	1,164,995	

Sources: Department of Health and Human Services, “Use of Public Health Service Set-Aside Authority for Fiscal Year 2013,” Report to Congress; and Department of Health and Human Services, “Use of Public Health Services Set-Aside Authority for Fiscal Year 2016,” Report to Congress.

Notes: NIH=National Institutes of Health; HRSA= Health Resources and Services Administration; CDC= Centers for Disease Control and Prevention; SAMHSA= Substance Abuse and Mental Health Services Administration; AHRQ= Agency for Healthcare Research and Quality; CMS= Centers for Medicare and Medicaid Services; ACF= Administration for Children and Families; ACL= Administration for Community Living; OS= Office of the Secretary.

Table 1 also shows the set-aside assessments and transfers for the current fiscal year (i.e., FY2016). These figures reflect the significant changes that the appropriators first made in FY2015 by returning most of the set-aside funding to NIH and eliminating any transfers to AHRQ, CDC, and HRSA. As a result, NIH has gone from being by far the largest net donor of set-aside funds to a net recipient of such funding. Meanwhile, AHRQ and CDC have experienced a significant loss of set-aside funding and are now both net donors of these funds.

The situation with AHRQ is of particular interest to many. From FY2003 through FY2014, AHRQ did not receive an annual discretionary appropriation. The agency was supported by set-aside funds and, in recent years, by amounts from other sources. In FY2015, however, AHRQ received a discretionary appropriation for the first time in more than a decade in lieu of receiving any set-aside funding. That continues to be the case in FY2016.¹⁵

Mandatory Funding, User Fees, and Collections

Although the bulk of PHS agency funding is provided through annual discretionary appropriations, agencies also receive mandatory funding, user fees, and third-party collections. As discussed below, these additional sources of funding are a substantial component of the budget of several PHS agencies.

Mandatory Appropriations

The ACA included numerous appropriations that together provided billions of dollars in mandatory spending¹⁶ to support specified grant programs and activities within HHS.¹⁷ A few

PHS agencies continue to receive these funds, which are itemized in the funding tables in this report.

The ACA also established and funded three multibillion dollar trust funds to help support PHS agency programs and activities. First, the ACA provided a total of \$11 billion in annual appropriations over the five-year period FY2011-FY2015 to the *Community Health Center Fund (CHCF)*.¹⁸ These funds help support the federal health centers program and the National Health Service Corps (NHSC), both of which are administered by HRSA. The Medicare Access and CHIP Reauthorization Act of 2015 (MACRA)¹⁹ appropriated two more years of funding for the CHCF; a total of \$3.910 billion for each of FY2016 and FY2017. A table summarizing each fiscal year's CHCF appropriation and the allocation of funds appears in Appendix A.

Second, the *Prevention and Public Health Fund (PPHF)*, for which the ACA provided a permanent annual appropriation, is intended to support prevention, wellness, and other public health programs and activities.²⁰ To date, CDC has received the majority of PPHF funds, while AHRQ, HRSA, and SAMHSA have received smaller amounts. The HHS Secretary transferred almost half of the FY2013 PPHF funds to CMS to support ACA implementation. A table showing the allocation of annual PPHF funding by agency since FY2010 is provided in Appendix B.

Finally, the *Patient-Centered Outcomes Research Trust Fund (PCORTF)* is supporting comparative effectiveness research over a 10-year period (FY2010-FY2019) with a mix of appropriations—some of which are offset by revenue from a fee imposed on health insurance policies and self-insured health plans—and transfers from the Medicare Part A and Part B trust funds.²¹ A portion of the PCORTF is allocated for AHRQ. More information on the PCORTF, including the appropriation and transfer formulas, is provided in Appendix C.

In addition to the ACA funding, HRSA, CDC, and IHS each receive mandatory funds from other sources. HRSA's Family-to-Family Health Information Centers Program has been funded by a series of mandatory appropriations since FY2007; CDC receives Medicaid funding to support the Vaccines for Children program; and both IHS and NIH receive mandatory funds for diabetes programs. These and other mandatory appropriations are itemized in the agency funding tables in this report.

User Fees

Several PHS agencies assess user fees on third parties to help fund their programs and activities. User fees collected by CDC, HRSA, and SAMHSA represent a very small portion of each agency's overall budget.²² In comparison, the industry user fees that FDA collects help finance a broad range of the agency's regulatory activities and account for a substantial and growing share of the agency's budget.

In 1992, the Prescription Drug User Fee Act (PDUFA)²³ established the first user fee program at FDA. Since PDUFA's enactment, Congress has created several other FDA user fee programs. These programs provide FDA with additional resources that allow it to hire more personnel and expedite the process of reviewing new product applications. Some user fees also pay for information technology infrastructure and postmarket surveillance of FDA-approved products. FDA's user fee programs now support the agency's regulation of prescription drugs, animal drugs, medical devices, tobacco products, and some foods, among other activities. The amount of user fees that FDA collects under these programs has increased steadily since PDUFA was enacted, both in absolute terms and as a share of FDA's

overall budget. In FY2016, user fees account for 43% of the agency's funding. More discussion of user fees is provided in the FDA section of this report and in Appendix D.

Collections

IHS supplements its annual discretionary appropriation with third-party collections from public and private payers. Most of these funds come from Medicare and Medicaid, which reimburse IHS for services provided to American Indians and Alaska Natives enrolled in these programs at facilities operated by IHS and the tribes. IHS also collects reimbursements from private health insurers. IHS collections (and reimbursements) are reflected in Table 8 of this report.

RECENT TRENDS IN PHS AGENCY FUNDING

Congress has taken a number of recent steps through both the annual appropriations process and the enactment of deficit-reduction legislation to reduce the growth in federal spending. These actions, which are briefly discussed below, have had an impact on the level of discretionary funding for several PHS agencies since FY2010.

Among the five PHS agencies that are funded through the LHHS appropriations act, AHRQ has witnessed a reduction in discretionary funding over the past six years. However, that reduction has been offset by the receipt of increasing amounts of mandatory funding. Discretionary funding for the other four agencies—CDC, HRSA, NIH, and SAMHSA—has fluctuated in recent years, dipping in FY2013 as a result of the sequestration of discretionary appropriations that fiscal year (see below). Both CDC and HRSA also have received increasing amounts of mandatory funding since FY2010, which has raised each agency's overall funding level.

FDA and IHS, which receive their discretionary funding through the Agriculture and the Interior/Environment appropriations acts, respectively, have seen their appropriations increase since FY2010. Both agencies also have witnessed a steady increase in funding from other sources; user fees at FDA, and third-party collections at IHS.

Impact of Budget Caps and Sequestration

In April 2011, lawmakers agreed to cuts in discretionary spending for a broad range of agencies and programs as part of negotiations to complete the FY2011 appropriations process and avert a government shutdown. Four months later, as part of negotiations to raise the debt ceiling,

Congress and the President then enacted the Budget Control Act of 2011 (BCA).²⁴ The BCA established enforceable discretionary spending limits, or caps, for defense and nondefense spending for each of FY2012 through FY2021, and provided for further annual spending reductions equally divided between the categories of defense and nondefense spending beginning in FY2013. Within each spending category, those further reductions are allocated proportionately to discretionary spending and mandatory spending, subject to

certain exemptions and special rules. All the spending summarized in this report falls within the nondefense category.

Under the BCA, the spending reductions are achieved through two different methods: (1) sequestration (i.e., an across-the-board cancellation of budgetary resources), and (2) lowering the BCA-imposed discretionary spending caps. The Office of Management and Budget (OMB) is responsible for calculating the percentages and amounts by which mandatory and discretionary spending are required to be reduced each year, and for applying the relevant exemptions and special rules.

Mandatory Spending

The BCA requires the mandatory spending reductions to be executed each year through a sequestration of all nonexempt accounts. Generally, the ACA and other mandatory funding discussed in this report is fully sequestrable at the applicable percentage rate for nonexempt nondefense mandatory spending (see Table 2), with the following key exceptions. First, the funds for the CDC-administered Vaccines for Children program come from Medicaid, which is exempt from sequestration. Second, CDC funding for the Energy Employees Occupational Illness Compensation Program Act (EEOICPA) and the World Trade Center Health Program also are exempt from sequestration. Third, under the sequestration special rules, cuts in CHCF funding for community health centers and migrant health centers and the cuts in mandatory diabetes funding for IHS are capped at 2% (see Table 2).

**Table 2. Sequestration of funding for PHS agency programs
FY2013-FY2017**

Mandatory Spending					
Nonexempt programs	5.1% ^a	7.2%	7.3%	6.8%	6.9%
Community & migrant health centers, IHS	2.0%	2.0%	2.0%	2.0%	2.0%
Discretionary Spending Nonexempt programs	5.0% ^a	NA ^b	NA ^b	NA ^b	NA ^b

Sources: OMB Report to the Congress on the Joint Committee Sequestration for Fiscal Year 2013, March 1, 2013; OMB Report to the Congress on the Joint Committee Reductions for Fiscal Year 2014, May 20, 2013; OMB Report to the Congress on the Joint Committee Reductions for Fiscal Year 2015, March 10, 2014; OMB Report to the Congress on the Joint Committee Reductions for Fiscal Year 2016, February 2, 2015; and OMB Report to the Congress on the Joint Committee Reductions for Fiscal Year 2017, February 9, 2016.

^a These percentages reflect adjustments made by the American Taxpayer Relief Act of 2012 (ATRA; P.L. 112-240), which amended the BCA by reducing the overall dollar amount that needed to be cut from FY2013 spending.

^b NA = not applicable.

While all the nonexempt PHS programs with mandatory funding were sequestered in FY2013 and FY2014, several of them avoided sequestration in FY2015 and/or FY2016 because they had no budgetary resources in place at the time the sequester was ordered by the President. The Maternal, Infant, and Early Childhood Home Visiting program, administered by HRSA, is one example of a program for which this occurred. The ACA authorized the home visiting program and funded it through FY2014 (see Table 7). Pursuant to the BCA, the President ordered the FY2015 sequestration on March 10, 2014. Because Congress and the President had yet to enact legislation extending funding for the home visiting program, there were no FY2015 budgetary resources to sequester.²⁵

Discretionary Spending

Under the BCA, FY2013 discretionary spending was also reduced through sequestration. However, for each of the remaining fiscal years (i.e., FY2014 through FY2021), the annual reductions in discretionary spending required under the BCA are to be achieved by lowering the discretionary spending caps by the total dollar amount of the required reduction. This means that the cuts within the lowered spending cap may be apportioned through the annual appropriations decisionmaking, rather than via an across-the-board reduction through sequestration.

FY2013 Sequestration

In general, PHS agency discretionary appropriations in FY2013 were fully sequestrable at the applicable percentage rate for nonexempt nondefense discretionary spending (see Table 2). As a result, each agency saw a dip in its discretionary funding for FY2013. OMB determined that FDA user fees for FY2013 were fully sequestrable, but concluded that IHS's third-party collections in FY2013 were exempt from sequestration.

FY2014-FY2017 Discretionary Spending Caps

Table 3 shows the original nondefense discretionary (NDD) spending caps for FY2014-FY2017 established by the BCA. For each of those four fiscal years, the BCA required the caps to be lowered by approximately \$37 billion to achieve the necessary reduction in NDD spending.

However, the Bipartisan Budget Act of 2013 (BBA13)²⁶ amended the BCA by establishing new levels for the FY2014 and FY2015 NDD spending caps, and eliminating the requirement for those caps to be reduced. While the BBA13 caps were set at a level that was lower than the original BCA caps (see Table 3), they were higher than the BCA-lowered caps that they replaced.

The Bipartisan Budget Act of 2015 (BBA15)²⁷ further amended the BCA by establishing new levels for the FY2014 and FY2015 NDD spending caps, and eliminating the requirement for those caps to be lowered. Once again, the BBA15 caps were set at a level that is below the original BCA caps for those two fiscal years (see Table 3), but is higher than the BCA-lowered caps that they replace.

The revised NDD caps allowed an additional \$26 billion for nondefense programs in FY2016 compared to the previous fiscal year. However, there is virtually no increase in NDD appropriations allowed by the FY2017 revised cap level. (The revised cap for FY2017 is only \$40 million above the revised cap for FY2016.)

Table 3. Nondefense discretionary spending limits billions of dollars

	FY2014	FY2015	FY2016	FY2017
Original caps under BCA	510.000	520.000	530.000	541.000
Revised caps under BBA13 and BBA15	491.773	492.356	518.491	518.531

Source: Budget Control Act of 2011 (P.L. 112-25); Bipartisan Budget Act of 2013 (P.L. 113-67, Division A); Bipartisan Budget Act of 2015 (P.L. 114-74).

Mandatory Funding Proposals for FY2017

The President's FY2017 budget includes a total of \$2.940 billion in proposed new mandatory funding for the PHS agencies: \$1.825 billion for NIH; \$590 million for SAMHSA; \$495 million for HRSA; and \$30 million for CDC. These amounts, which are discussed later in this report, would be used to supplement—and in one case replace—discretionary funding for existing programs, or provide funding for new initiatives. It will be up to Congress to decide whether to pass legislation to provide these funds.

The use of mandatory funding, including amounts provided by the ACA, has become an important component of PHS agency budgeting in recent years. Mandatory funds are not controlled by the annual appropriations process and do not count towards the discretionary spending caps.

REPORT ROADMAP

The remainder of this report consists of seven sections, one for each PHS agency beginning with AHRQ.²⁸ Each section includes an overview of the agency's statutory authority and principal activities, and a brief summary of recent trends in the agency's funding. This material is accompanied by a detailed funding table showing the agency's FY2015 and FY2016 funding levels and the FY2017 budget request. The amounts in the funding tables in this report are taken from the departmental and agency budget documents submitted to the appropriations committees, as well as agency operating plans.²⁹

The funding tables show the post-sequestration amounts for the accounts that were subject to sequestration in FY2015 and FY2016. The amounts shown for the FY2017 request do not reflect sequestration.

The funding tables are formatted in a similar, though not identical, manner. The formatting generally matches the way in which each agency's funding is presented in the congressional budget documents. Each table shows the funding for all the agency's budget accounts and, typically, for selected programs and activities within those accounts. These amounts are summed to give the agency's total, or *program level*, funding. At the bottom of the table any user fees, set-aside funds, ACA funds, and other nondiscretionary amounts are subtracted from the program level to give the agency's *discretionary budget authority* (i.e., annual discretionary appropriations).

The tables for AHRQ, CDC, HRSA, and SAMHSA include non-add entries—italicized and in parentheses—to indicate the contribution of funding to specific accounts from sources other than the agency's discretionary appropriations. Almost all of the CDC accounts, for example, are funded with discretionary appropriations plus amounts from other sources (see Table 5).

The use of a dash in the funding tables generally means “not applicable.” Either the activity or program was not authorized or there was no mandatory funding provided for that fiscal year. In contrast, a zero usually indicates that congressional appropriators had chosen not to appropriate any discretionary funds that year or, in the case of the FY2017 budget request, that no discretionary funding was requested.

It is important to keep in mind that the PHS agency funding tables that appear in budget documents and appropriations committee reports, as well as the tables in this report, show only the amount of evaluation set-aside funds received. They do not reflect the amount of funding assessed on agency accounts. As a result, the funding tables for the PHS agencies subject to an assessment give a somewhat distorted view of their available budgetary resources. This effect is particularly significant in the case of the three agencies—CDC, HRSA, and NIH—that are subject to a significant assessment under the evaluation set-aside authority (see Table 1). NIH, for example, is assessed approximately \$700 million annually. While the funding table for NIH shows the transfer (i.e., receipt) of set-aside funds, which count towards the agency’s overall program level funding, the amounts shown for each agency account have not been reduced to reflect the assessment. Thus, NIH appears to have about \$700 million more than is in fact the case.

AGENCY FOR HEALTHCARE RESEARCH AND QUALITY (AHRQ)³⁰

Agency Overview

AHRQ supports research designed to improve the quality of health care, increase the efficiency of its delivery, and broaden access to health services.³¹ Specific research efforts are aimed at reducing the costs of care, promoting patient safety, measuring the quality of health care, and improving health care services, organization, and financing. AHRQ is required to disseminate its research findings to health care providers, payers, and consumers, among others. In addition, the agency collects data on health care expenditures and utilization through the Medical Expenditure Panel Survey (MEPS) and the Healthcare Cost and Utilization Project (HCUP).

Health Costs, Quality and Outcomes (HCQO) Research Areas

Health Information Technology (HIT) Research. Research evaluating HIT and its impact on the quality and efficiency of health care.

Patient Safety. Research on reducing and preventing medical errors, with a focus on health care-associated infections (HAIs).

Health Services Research, Data, and Dissemination. Research on quality of health care that spans multiple priority areas including, for example, the annual National Healthcare Quality and National Healthcare Disparities Reports.

U.S. Preventive Services Task Force (USPSTF). AHRQ provides the USPSTF with scientific, administrative, and other types of support, although the Task Force is an independent panel of national experts.

Source: CRS Analysis and the FY2017 HHS Budget in Brief. <http://www.hhs.gov/about/budget/fy2017/budget-in-brief/ahrq/index.html>.

AHRQ has evolved from a succession of agencies concerned with fostering health services research and health care technology assessment. The Omnibus Budget Reconciliation Act of 1989 (P.L. 101-239) added a new PHSA Title IX and established the Agency for Health Care Policy and Research (AHCPR), a successor agency to the former National Center for Health Services Research and Health Care Technology Assessment (NCHSR). AHCPR

was reauthorized in 1992 (P.L. 102 410). On December 6, 1999, President Clinton signed the Healthcare Research and Quality Act of 1999 (P.L. 106-129), which renamed AHCPR as the Agency for Healthcare Research and Quality (AHRQ) and reauthorized appropriations for its programs and activities through FY2005. Congress has yet to reauthorize the agency's funding. Despite the expired authorization of appropriations, AHRQ continues to get annual funding.

The AHRQ budget is organized according to three program areas: (1) Healthcare Costs, Quality and Outcomes (HCQO) Research; (2) MEPS; and (3) program support. HCQO research currently focuses on four priority areas, summarized in the text box below.

From FY2003 through FY2014, AHRQ did not receive its own annual discretionary appropriation. Instead, the agency largely relied on the PHS evaluation set-aside to fund its activities and programs. In recent years AHRQ also has received mandatory funds from the PPHF and the PCORTF (see Appendix B and Appendix C). In FY2015, AHRQ received its own discretionary appropriation for the first time in more than a decade in lieu of any set-aside funding.³² This trend continued in FY2016 with the agency receiving its own discretionary appropriation and no set-aside funds.

Table 4. Agency for Healthcare Research and Quality (AHRQ)
(millions of dollars, by fiscal year)

Program or Activity	2015	2016	2017 Request

Notes: Individual amounts may not add to subtotals or totals due to rounding.

^a Formerly "Crosscutting Activities;" also formerly "Research Innovations."

^b AHRQ receives funds transferred from the PCORTF to carry out PHSA Section 937, which requires the dissemination of the results of patient-centered outcomes research carried out by the Patient Centered Outcomes Research Institute (PCORI) and other "government-funded research relevant to comparative clinical effectiveness research." For FY2011-FY2013, the PCORTF transfer supplemented the agency's set-aside funding for its patient-centered health research program. Since FY2014, however, AHRQ's patient-centered health research program has been entirely funded by the PCORTF transfer, which is now shown as its own separate budget line. AHRQ's budget documents no longer list patient-centered health research as a separate program area.

Recent Trends in Agency Funding

Since FY2010, AHRQ's budget has increased from \$403 million to \$428 million (+\$25 million), with transfers from PCORTF growing from \$8 million in FY2011 to \$94 million in

FY2016. Discretionary sources of funding shifted from set-aside transfers to the agency's own discretionary appropriation in both FY2015 and FY2016, and ACA mandatory funds have been a prominent and increasing source of funding for the agency since FY2010. AHRQ's program level had been increasing steadily between FY2011 and FY2015, with decreases in discretionary funding being more than offset by transfers of PCORTF funds. However, in FY2016, the total program level for the agency decreased for the first time since FY2011, despite an increasing PCORTF transfer (see Table 4).

CENTERS FOR DISEASE CONTROL AND PREVENTION (CDC)³³

Agency Overview

CDC's mission is "to protect America from health, safety and security threats, both foreign and in the [United States]." CDC is organized into a number of centers, institutes, and offices, some focused on specific public health challenges (e.g., chronic disease prevention, injury prevention), and others focused on general public health capabilities (e.g., surveillance and laboratory services).³⁵ In addition, the Agency for Toxic Substances and Disease Registry (ATSDR) is headed by the CDC Director and is discussed in this section.

Many CDC activities are not specifically authorized but are based in broad, permanent authorities in the PHSA.³⁶ Four CDC operating divisions are explicitly authorized. The National Institute for Occupational Safety and Health (NIOSH) was permanently authorized by the Occupational Safety and Health Act of 1970.³⁷ The National Center on Birth Defects and Developmental Disabilities (NCBDDD) was established in PHSA Section 317C by the Children's Health Act of 2000.³⁸ The National Center for Health Statistics (NCHS) was established in PHSA Section 306 by the Health Services Research, Health Statistics, and Medical Libraries Act of 1974.³⁹ ATSDR was established by the Comprehensive Environmental Response, Compensation and Liability Act of 1980 (CERCLA, the "Superfund" law).⁴⁰ Authorizations of appropriations for NCBDDD, NCHS, and ATSDR have expired, but the programs continue to receive annual appropriations.

CDC provides about \$5 billion per year in grants to state, local, municipal, tribal, and foreign governments, and to academic and non-profit entities.⁴¹ It has few regulatory responsibilities.

Recent Trends in Agency Funding

Between FY2010 and FY2016, the total program level for CDC/ATSDR increased from \$10.88 billion to \$11.78 billion. During that time period, CDC/ATSDR budget authority decreased by 3% from \$6.5 billion in FY2010 to \$6.3 billion in FY2016. Table 5 presents funding levels for CDC programs for FY2015 through the FY2017 request. In addition to annual discretionary appropriations, program level amounts for recent years include funds from the following four mandatory appropriations: (1) the Vaccines for Children (VFC) program;⁴² (2) NIOSH activities to support the Energy Employees Occupational Illness Compensation Program Act (EEOICPA);⁴³ (3) the World Trade Center Health Program

(WTCHP);⁴⁴ and (4) appropriations provided under ACA, principally through the PPHF.⁴⁵ CDC receives a small amount of funds from authorized user fees, and may also receive funds through the PHS set-aside, supplemental appropriations, and other transfers.

When considering funding trends for CDC/ATSDR, it is useful to consider mandatory and discretionary funds separately. For example, for FY2016, the CDC/ATSDR total operating budget, or program level, is \$11.78 billion. Of this amount,

- \$6.27 billion (53%) is composed of discretionary funds (i.e., budget authority) for CDC provided in the LHHS appropriations act;
- \$5.42 billion (46%) is composed of mandatory funds for CDC and ATSDR programs, namely the VCF, EEOICPA, and WTCHP, and from the ACA (principally from the PPHF);
- \$75 million (<1%) is discretionary funds for ATSDR provided in the Interior/Environment appropriations act; and
- \$17 million (<1%) is from authorized user fees and other transfers.

Many of CDC's PPHF-funded activities also receive discretionary appropriations. Exceptions include the Preventive Health and Health Services Block Grant, and the Lead Poisoning Prevention Program, which were funded solely through PPHF distributions for FY2016.⁴⁶ For more discussion on the allocation of annual PPHF funding, see Appendix B.

Sources: CDC and ATSDR congressional budget justifications and related documents for FY2016 and FY2017, <http://www.cdc.gov/fmo>.

Notes: Individual amounts may not add to subtotals or totals due to rounding.

Amounts in this table do not include emergency supplemental Ebola response funding for FY2015-FY2019 provided in P.L. 113-235. These funds are discussed in CRS Report R44460, *Zika Response Funding: In Brief*; and at CDC, “FY 2015–2019 Ebola Response Funding,” <http://www.cdc.gov/budget/ebola/index.html>.

PHSSEF is Public Health and Social Services Emergency Fund, a fund used by appropriators to provide the Secretary with ongoing or one-time emergency funding, such as for the response to influenza epidemics. STI is sexually transmitted infection.

^a The Vaccines for Children (VFC) program provides free pediatric vaccines to doctors who serve eligible (generally low-income) children. VFC is funded entirely as an entitlement through federal Medicaid appropriations and is exempt from sequestration. Amounts for FY2015 through the FY2017 request are estimates.

^b ACA Section 4306 appropriated \$25 million for a childhood obesity demonstration project, <http://www.cdc.gov/obesity/childhood/researchproject.html>. The Medicare Access and CHIP Reauthorization Act of 2015 (MACRA, P.L. 114-10) appropriated additional funding for the project; \$10 million for the two-year period FY2016–FY2017.

^c New mandatory funding for FY2017 is proposed for CDC to assist state health departments in implementing comprehensive suicide prevention programs.

^d Emergency supplemental appropriations for FY2015 for the response to the 2014 Ebola outbreak in West Africa, provided in P.L. 113-164. See note above re: subsequent emergency appropriations for the Ebola response.

^e For several years the budget request has called for elimination of the Preventive Health and Health Services Block Grant (also called the “Prevention Block Grant”). For each of FY2015 and FY2016, Congress provided it with \$160 million from the PPHF.

^f Amounts are estimated federal obligations.

^g ACA Section 10323(b) appropriated \$23 million for the period FY2010-FY2014, and \$20 million for each five-year period thereafter, in no-year funding for the early detection of certain medical conditions related to environmental health hazards in Libby, Montana. The amount presented (i.e., \$19 million for FY2015 through FY2019) reflects sequestration as required for non-defense mandatory spending; see Table 2.

In December 2014 Congress provided \$1.771 billion in FY2015 emergency supplemental appropriations to CDC for response to the Ebola outbreak. The funds, which are available through FY2019, are to be used for both domestic and international activities. CDC has not presented these funds within its general budget, and they are not presented in Table 5.⁴⁷ However, the table does include \$30 million provided to CDC's Global Health Program from an earlier Ebola supplemental.

FOOD AND DRUG ADMINISTRATION (FDA)⁴⁸

Agency Overview

FDA regulates the safety of human foods, dietary supplements, cosmetics, and animal foods; and the safety and effectiveness of human drugs, biological products (e.g., vaccines), medical devices, and animal drugs. It also regulates the manufacture of radiation-emitting products to protect the public from hazardous levels of radiation. In 2009, Congress gave FDA the authority to regulate the manufacture, marketing, and distribution of tobacco products in order to protect public health.

Seven centers within FDA represent the broad program areas for which the agency has responsibility: the Center for Biologics Evaluation and Research (CBER), the Center for Devices and Radiological Health (CDRH), the Center for Drug Evaluation and Research (CDER), the Center for Food Safety and Applied Nutrition (CFSAN), the Center for Veterinary Medicine (CVM), the National Center for Toxicological Research (NCTR), and the Center for Tobacco Products (CTP). Several other offices have agency-wide responsibilities.

The Federal Food, Drug, and Cosmetic Act (FFDCA) is the principal source of FDA's statutory authority.⁴⁹ FDA is also responsible for administering certain provisions in other laws, most notably the PHSA.⁵⁰ Although the FDA's authorizing committees in Congress are the committees with jurisdiction over public health issues—the Senate Committee on Health, Education, Labor, and Pensions, and the House Committee on Energy and Commerce—FDA's assignment within the appropriations committees reflects its origin as part of the Department of Agriculture. The Senate and House appropriations subcommittees on Agriculture, Rural Development, FDA, and Related Agencies have jurisdiction over FDA's budget, even though the agency has been part of various federal health agencies (HHS and its predecessors) since 1940.

FDA's budget has two funding streams: annual appropriations (i.e., discretionary budget authority, or BA) and industry user fees. In FDA's annual appropriation, Congress sets both the total amount of appropriated funds and the amount of user fees that the agency is authorized to collect and obligate for that fiscal year. Appropriated funds are largely for the Salaries and Expenses account, with a smaller amount for the Buildings and Facilities account. The several different user fees, which account for 43% of FDA's total FY2016 program level, contribute only to the Salaries and Expenses account.

The largest and oldest FDA user fee that is linked to a specific program was first authorized by the Prescription Drug User Fee Act (PDUFA, P.L. 102-571) in 1992. Appendix D presents the authorizing legislation for current FDA user fees, sorted by the dollar amount

they contribute to the agency's FY2016 budget. After PDUFA, Congress added user fee authorities regarding medical devices, animal drugs, animal generic drugs, tobacco products, priority review, food reinspection, food recall, voluntary qualified food importer, generic drugs, biosimilars, and, most recently, outsourcing facilities (related to drug compounding) and some wholesale distributors and third-party logistics providers (related to pharmaceutical supply chain security).⁵¹ Each of the medical product fee authorities requires reauthorization every five years. Several indefinite authorities apply to fees for mammography inspection, color additive certification, export certification, and priority review vouchers.⁵²

Recent Trends in Agency Funding

Between FY2010 and FY2016, FDA's funding increased from \$3.1 billion to \$4.7 billion. Although discretionary appropriations increased by 16% over that time period, user fee revenue more than doubled. In FY2016, user fees account for 43% of FDA's total funding compared with 24% in FY2010.

Sources: Prepared by CRS based on congressional budget justification documents and the HHS *Budget in Brief*, available at <http://www.hhs.gov/budget/>.

Notes: Individual amounts may not add to subtotals or totals due to rounding.

Consistent with the Administration and congressional committee formats, each program area includes funding designated for the responsible FDA center (e.g., the Center for Drug Evaluation and Research or the Center for Food Safety and Applied Nutrition) and the portion of effort budgeted for the agency-wide Office of Regulatory Affairs to commit to that area. It also apportions user fee revenue across the program areas as indicated in the Administration's request (e.g., 90% of the animal drug user fee revenue is designated for the animal drugs and feeds program, with the rest going to headquarters and Office of the Commissioner, GSA rent, and other rent and rent-related activities categories).

^a This column shows the FY2015 actual amounts. A "0" in this column does not reflect a lack of authorization for that program. For example, user fees for food are listed as "0," meaning that no fees were collected in FY2015 for the food program, but user fees for food were authorized in the FY2015 enacted bill.

^b The FY2015 Agriculture appropriations act provided an additional \$25 million to FDA for Ebola response and preparedness activities. Adding this amount to the FDA appropriations brought BA to \$2,633 million and the total program level to \$4,536 million for FY2015.

^c This total does not include the \$75 million in proposed new mandatory funding for the Vice President's Cancer Moonshot Initiative.

^d The FY2015 enacted bill included \$1 million for fees related to pharmacy compounding that the President's request had not included in the FY2015 request submission.

^e The FY2016 enacted bill included \$1 million for fees related to pharmacy compounding (Congressional Budget Office estimate) that the President's request had not included in the FY2016 request submission.

^f For user fees in the Administration's FY2017 request, this column shows only those that have been authorized. Including the \$202 million in proposed user fees, the President's total user fee request is \$2.286 billion, yielding a total program level request of \$5.029 billion.

The President's FY2017 budget request was for a *total program level* of \$4.826 billion, an increase of \$81 million (+2%) from the FY2016 total program level of \$4.745 billion (see Table 6). The FY2017 budget request includes \$2.743 billion for budget authority, an increase of \$15 million (+0.5%) compared to the FY2016 enacted level of \$2.728 billion, and \$2.084 billion for user fees, an increase of \$66 million (+3%) compared to the FY2016 enacted level of \$2.017 billion. In addition to the \$2.084 billion in user fees from currently authorized programs, the President requested \$202 million in as yet unauthorized fees to support export certification, food facility registration and inspection, food import, international courier,

cosmetics, and food contact substance notification activities. With those proposed fees, the President's total user fee request was \$2.286 billion, bringing the total program level request to \$5.029 billion. The FY2017 request also included \$75 million in new mandatory resources to support the Cancer Moonshot Initiative.⁵³

HEALTH RESOURCES AND SERVICES ADMINISTRATION (HRSA)⁵⁴

Agency Overview

HRSA is the federal agency charged with improving access to health care for those who are uninsured, isolated, or medically vulnerable. The agency currently awards funding to more than 3,000 grantees, including community-based organizations; colleges and universities; hospitals; state, local, and tribal governments; and private entities to support health services projects, such as training health care workers or providing specific health services.⁵⁵ HRSA also administers the health centers program, which provides grants to non-profit entities that provide primary care services to people who experience financial, geographic, cultural, or other barriers to health care.⁵⁶

HRSA Bureaus

The *Bureau of Primary Health Care* administers the Health Centers program, authorized under Title III of the PHSA. Community and other health centers provide access to primary care for individuals who are low-income, uninsured, or living where health care is scarce.

The *Bureau of Health Workforce* administers scholarship, loan and loan repayment programs that help underserved communities recruit and retain health professionals. These programs include the National Health Service Corps, NURSE Corps, and the Faculty Loan Repayment Program. The bureau also administers a number of programs for health professions training and development of diversity and cultural competence in the health workforce. These programs include the Oral Health Training Program, the Nursing Workforce Diversity Program, the Children's Hospitals Graduate Medical Education Program, the Teaching Health Center Graduate Medical Education program funded under ACA, and the Scholarships for Disadvantaged Students Program. The Bureau of Health Professions also administers the National Practitioner and Healthcare Integrity Protection Data Banks and the National Center for Health Workforce Analysis. Titles III, VII, and VIII of the PHSA authorize programs in this bureau.

The *Maternal and Child Health Bureau* administers the Maternal and Child Health Block Grant and other programs that support the infrastructure for maternal and child health services, including the Maternal, Infant, and Early Childhood Home Visiting Program that was authorized and funded by ACA. These programs are authorized in Title V of the Social Security Act (SSA). This bureau also administers Healthy Start, newborn hearing screening, autism, and other programs authorized under Titles III, XI, XII, and XIX of the PHSA.

The *HIV/AIDS Bureau* administers the Ryan White HIV/AIDS program, which is the largest discretionary grant program within HRSA and is focused on HIV/AIDS care. The Ryan White HIV/AIDS program administers grant programs that provide early intervention, minority, and family services. It also administers the AIDS Drug Assistance Program (ADAP). Title XXVI of the PHSA authorizes the Ryan White HIV/AIDS programs.

The *Healthcare Systems Bureau* provides national leadership and direction in targeted areas, such as organ and bone marrow transplantation, poison control centers, and others. It also administers the 340B drug pricing program. Titles III and XII of the PHSA authorize programs in this bureau.

Source: HRSA website, <http://www.hrsa.gov/about/organization/bureaus/index.html>.

HRSA is organized into five bureaus (see text box below) and ten offices. Some offices focus on specific populations or health care issues (e.g., Office of Women’s Health, Office of Rural Health Policy), while others provide agency-wide support or technical assistance to HRSA’s regional offices (e.g., Office of Planning, Analysis and Evaluation; Office of Regional Operations).⁵⁷

As noted in the text box, the majority of HRSA’s programs are authorized by the PHSA;⁵⁸ others are authorized by the SSA. Additionally, Section 427(e) of the Federal Mine Safety and Health Amendments Act (P.L. 95-164) authorizes the Black Lung Program, which supports clinics that provide services to retired coal miners and others.

Recent Trends in Agency Funding

HRSA funding increased from \$8.1 billion in FY2010 to \$10.8 billion in FY2016 despite a reduction in its discretionary appropriation during that time (see **Table 7**). Specifically, discretionary appropriations declined by about 17%; falling from \$7.5 billion to \$6.2 billion. Much of the decline in discretionary appropriations occurred because of the loss of discretionary appropriations for the National Health Service Corps (NHSC) and the elimination of the congressional earmark program that supported health care facility construction and renovation.

The overall growth in HRSA’s funding was primarily driven by increasing amounts from the CHCF, which more than offset the decline in discretionary funding. CHCF funding has partially supplanted (i.e., replaced) discretionary health center funding and has become the sole source of funding for the NHSC program, which has not received an annual discretionary appropriation since FY2011.

Source: Prepared by CRS based on congressional budget justification documents and the HHS *Budget in Brief*, available at <http://www.hhs.gov/budget/>; and from P.L. 114-10.

Notes: Individual amounts may not add to subtotals or totals due to rounding.

^a Includes funds appropriated in MACRA (P.L. 114-10).

^b Training for Diversity includes the following programs: Centers for Excellence, Scholarships for Disadvantaged Students, and the Health Careers Opportunity Program.

^c Interdisciplinary, Community-based Linkages includes the following programs: Area Health Education Centers (AHEC), Geriatric Programs, and Mental and Behavioral Health Education and Training. In FY2017, the President's Budget does not request funding for the Area Health Education Center program.

^d Nursing Workforce Development includes the following programs: NURSE Corps (formerly the Nursing Education Loan Repayment and Scholarship Program); Advanced Nursing Education; Nursing Workforce Diversity; Nurse Education, Practice, Quality and Retention; Nurse Faculty Loan Program; and Comprehensive Geriatric Education.

^e Other Health Workforce Programs include Health Care Workforce Assessment, and Oral Health Training.

^f P.L. 113-93 provided \$2.5 million for this program for FY2015, which was repealed when P.L. 114-10 provided a full year of funding (\$5 million) for this program for FY2015.

^g Other Maternal and Child Health Programs include Autism and Other Developmental Disorders, Traumatic Brain Injury, Sickle Cell Services Demonstration, Universal Newborn Hearing Screening, Emergency Medical Services for Children, and Heritable Disorders.

^h Health Care Systems Programs include Organ Transplantation, National Cord Blood Inventory, C.W. Bill Young Cell Transplantation Program, and Poison Control Centers.

With CHCF funding set to expire at the end of FY2015, Congress included two more years of CHCF funding in the Medicare Access and CHIP Reauthorization Act of 2015 (MACRA);⁵⁹ see Table 7 and Appendix A. MACRA also extended funding for other HRSA programs that were established and initially funded by the ACA; notably, the Maternal, Infant, and Early Childhood Home Visiting Program and the Teaching Health Center Program.

INDIAN HEALTH SERVICE (IHS)⁶⁰

Agency Overview

IHS provides health care for approximately 2.2 million eligible American Indians/Alaska Natives through a system of programs and facilities located on or near Indian reservations, and through contractors in certain urban areas. IHS provides services to members of 566 federally recognized tribes either directly or through facilities and programs operated by Indian Tribes or Tribal Organizations through self-determination contracts and self-governance compacts authorized in the Indian Self-Determination and Education Assistance Act (ISDEAA).⁶¹

The Snyder Act of 1921 provides general statutory authority for IHS.⁶² In addition, specific IHS programs are authorized by two acts: the Indian Sanitation Facilities Act of 1959⁶³ and the Indian Health Care Improvement Act (IHCIA).⁶⁴ The Indian Sanitation Facilities Act authorizes the IHS to construct sanitation facilities for Indian communities and homes; and IHCIA authorizes programs such as urban health, health professions recruitment, and substance abuse and mental health treatment, and permits IHS to receive reimbursements from Medicare, Medicaid, the State Children's Health Insurance Program (CHIP), the Department of Veterans Affairs (VA), and third-party insurers.

As discussed earlier, IHS receives its appropriations through the Interior/Environment appropriations act. IHS funding is not subject to the PHS set-aside.

Recent Trends in Agency Funding

IHS's funding, which includes discretionary appropriations and collections from third-party payers of health care, increased between FY2010 and FY2016 from \$5.1 billion to \$6.2 billion (see Table 8). This increase was driven both by increased discretionary appropriations, which rose from \$4.1 billion to \$4.8 billion, and by increased collections, which rose from \$891 million to \$1.1 billion. Much of the funding increase was used to support clinical services. Discretionary appropriations, in particular, have increased funding for purchased/referred care, a subset of the clinical services budget line that applies to funds used to refer patients to an outside provider when the IHS cannot provide a service within its system. Funding allocated for contract support costs has also increased since FY2014.

**Table 8. Indian Health Service (IHS)
(millions of dollars, by fiscal year)**

Less Funds from Other Sources			
Collections	1,151	1,194	1,194
Rental of Staff Quarters	8	9	9
Special Diabetes Program for Indians ^d	150	150	150
Tribal Crisis Response Fund	—	—	15 ^h
Indian Health Professions Expansion	—	—	10
Total, Discretionary Budget Authority	4,642	4,808	5,185

Sources: Prepared by CRS based on congressional budget justification documents and the HHS *Budget in Brief*, available at <http://www.hhs.gov/budget/>.

Notes: Individual amounts may not add to subtotals or totals due to rounding.

^a Includes \$1,151 million in collections from Medicare, Medicaid, CHIP, the Department of Veterans Affairs, private insurance, and other programs.

^b Includes an estimated \$1,194 million in collections from Medicare, Medicaid, CHIP, the Department of Veterans Affairs, private insurance, and other programs.

^c This was previously referred to as “Contract Health Services.”

^d PHSA Sec. 330C provides an annual appropriation of \$150 million through FY2017 for this program. As discussed earlier in this report, these mandatory funds were subject to a 2% sequestration in FY2013 and FY2014.

^e Beginning in FY2016, Contract Support Costs were funded as an indefinite discretionary appropriation. For FY2018 and beyond, the President’s Budget includes a proposal to reclassify Contract Support Costs as a mandatory three-year appropriation.

^f Includes \$8 million that IHS received from rental of staff quarters.

^g Includes \$9 million that IHS expects to receive from rental of staff quarters.

^h These funds would be available as part of a new Administration initiative to improve Tribal Behavioral Health. The initiative would include crisis response funds for Indian Tribes experiencing behavioral health crises and would increase funding for IHS scholarship and loan repayment for behavioral health providers.

Contract support costs are funds that Indian Tribes and Tribal Organizations receive, in addition to operating funds, when they operate a facility or program under an ISDEAA contract or compact. According to the U.S. Supreme Court, these costs must be fully funded even if Congress does not appropriate sufficient funds to cover all tribes’ contract support

costs. According to IHS, beginning in FY2016, the amount allocated for contract support costs is sufficient for the contracts and compacts that IHS enters into. Given the ruling that stated that these are required costs, the President's Budget includes a proposal to reclassify contract support costs as a mandatory three-year appropriation.⁶⁵

NATIONAL INSTITUTES OF HEALTH (NIH)⁶⁶

Agency Overview

NIH is the primary agency of the federal government charged with performing and supporting biomedical and behavioral research. Its activities cover a wide range of basic, clinical, and translational research, as well as research training and health information collection and dissemination. The agency is organized into 27 research institutes and centers, headed by the NIH Director. The Office of the Director (OD) sets overall policy for NIH and coordinates the programs and activities of all NIH components, particularly in areas of research that involve multiple institutes. The institutes and centers (collectively called ICs) focus on particular diseases, areas of human health and development, or aspects of research support. Each IC plans and manages its own research programs in coordination with the Office of the Director.

The bulk of NIH's budget, about 81%, goes out to the extramural research community through grants, contracts, and other awards. The funding supports research performed by more than 30,000 individuals who work at more than 2,500 universities, hospitals, medical schools, and other research institutions around the country and abroad.⁶⁷ A smaller proportion of the budget, about 11%, supports the intramural research programs of the ICs, funding research performed by NIH scientists and non-employee trainees in the NIH laboratories and Clinical Center. The remaining 6% funds various research management, support, and facilities' needs.

NIH derives its statutory authority from the PHSA. Title III, Section 301 of the PHSA grants the HHS Secretary broad permanent authority to conduct and sponsor research. In addition, Title IV, "National Research Institutes," authorizes in greater detail various activities, functions, and responsibilities of the NIH Director and the institutes and centers. All of the ICs are covered by specific provisions in the PHSA, but they vary considerably in the amount of detail included in the statutory language. There are few time-and-dollar authorization levels specified for individual activities. Congress mandated a significant reorganization of IC responsibilities in the FY2012 Consolidated Appropriations Act (P.L. 112-74, Division F) by creating a new National Center for Advancing Translational Sciences (NCATS) and eliminating the National Center for Research Resources (NCRR). Activities relating to translational sciences from NCRR and many other ICs were consolidated in NCATS, and NCRR's other programs were moved to several other ICs and the OD.

NIH gets almost its entire funding (99.5%) from annual discretionary appropriations. As shown in Table 9, the annual LHHs appropriations act provides separate appropriations to 24 of the ICs, the OD, and the Buildings and Facilities account. One of the ICs (Environmental Health Sciences) also receives funding from the Interior/Environment appropriations act. In

addition, NIH receives a mandatory annual appropriation (\$150 million) for type 1 diabetes research.

Sources: Funding amounts for FY2015 and FY2016 are taken from the FY2016 Justification of Estimates for Appropriation Committees, Vol. 1, Overview, table on “Budget Request for Institute and Center,” p.85 at <http://officeofbudget.od.nih.gov/br.html>.

Notes: Totals may differ from the sum of the components due to rounding.

^a Amounts for the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) include \$150 million in mandatory funding for type 1 diabetes research (see note e).

^b Amounts for National Institute of General Medical Sciences (NIGMS) include the PHS set-aside funds.

^c Reflects name change from National Center for Complementary and Alternative Medicine to National Center for Complementary and Integrative Health; provision included in P.L. 113-235.

^d Mandatory funds available to NIDDK for type 1 diabetes research under PHS §330B (provided by P.L. 114-10 for FY2016 and FY2017).

Recent Trends in Agency Funding

Between FY1994 and FY1998, funding for NIH grew from \$11.0 billion to \$13.7 billion in nominal terms. Over the next five years, Congress doubled the NIH budget to \$27.2 billion in FY2003. In each of these years, the agency received annual funding increases of 14% to 16%. Since FY2003, however, NIH funding has increased more gradually in nominal dollars. Funding peaked in FY2010 before declining in FY2011 through FY2013 with small increases in subsequent years. The NIH program level in FY2016 is \$32.311 billion.

For FY2017, the Obama Administration requests an NIH program level total of \$33.136 billion, an increase of \$825 million (2.6%) over FY2016. The FY2017 program level request includes \$847 million in PHS set-aside funds and \$1.825 billion in proposed new mandatory funding. The FY2017 request includes \$755 million for the Vice President's Cancer Moonshot, of which \$680 million is allocated for the National Cancer Institute, and \$75 million would be transferred from NIH to FDA.

SUBSTANCE ABUSE AND MENTAL HEALTH SERVICES ADMINISTRATION (SAMHSA)⁶⁸

Agency Overview

SAMHSA is the lead federal agency for increasing access to behavioral health services. It supports community-based mental health and substance abuse treatment and prevention services through formula grants to the states and U.S. territories and through competitive grant programs that fund states, territories, tribal organizations, local communities, and private entities. SAMHSA also engages in a range of other activities, such as technical assistance, data collection, and workforce development.

SAMHSA and most of its programs and activities are authorized under Title V of the PHSA, which organizes SAMHSA in three centers:

- Center for Substance Abuse Treatment (CSAT)⁶⁹
- Center for Substance Abuse Prevention (CSAP)⁷⁰
- Center for Mental Health Services (CMHS)⁷¹

Each center has general statutory authority, called Programs of Regional and National Significance (PRNS), under which it has established grant programs for states and communities to address their important substance abuse and mental health needs. PHSA Title V also authorizes a number of specific grant programs, referred to as categorical grants.

SAMHSA's two largest grant programs are separately authorized under PHSA Title XIX, Part B. The Community Mental Health Services block grant falls within CMHS.⁷² The full amount of the Substance Abuse Prevention and Treatment block grant falls within CSAT, although no less than 20% of each state's block grant must be used for prevention.⁷³

In addition to the three statutorily defined centers, SAMHSA's budget reflects a fourth category, "health surveillance and program support," for other activities such as collecting data, providing statistical and analytic support, raising public awareness, developing the

behavioral health workforce, and maintaining the National Registry of Evidence-based Programs and Practices.⁷⁴

The last comprehensive reauthorization of SAMHSA and its programs occurred in 2000 as part of the Children’s Health Act,⁷⁵ which also added “charitable choice” provisions allowing religious organizations to receive funding for substance abuse prevention and treatment services without altering their religious character.⁷⁶ Since 2000, Congress has expanded some of SAMHSA’s programs and activities without taking up comprehensive reauthorization. Although authorizations of appropriations for most of SAMHSA’s grant programs expired at the end of FY2003, many of these programs continue to receive annual discretionary appropriations.

Recent Trends in Agency Funding

Over the past 10 years (FY2007–FY2016), SAMHSA’s program-level funding has increased by 12%, from \$3.3 billion to \$3.7 billion. It has not, however, increased every year. For example, it decreased from FY2012 (\$3.6 billion) to FY2013 (\$3.4 billion) due to sequestration, then rebounded in FY2014 (\$3.6 billion).

Relative to FY2016, SAMHSA’s FY2017 request would increase program-level funding by 16% (to \$4.3 billion) while decreasing discretionary budget authority by 3% (to \$3.5 billion); see Table 10. It would make up the difference with increased PHS set-aside funds, increased PPHF transfers, and new mandatory funding proposed for FY2017 and FY2018. The proposed new mandatory funding would support three programs: (1) State Targeted Response Cooperative Agreements, which would aim to increase access to opioid addiction treatment by addressing the most commonly identified barriers to treatment; (2) Evidence-based Early Interventions, which would provide formula grants to states to support early interventions for individuals with serious mental illness; and (3) Cohort Monitoring and Evaluation of Medication-Assisted Treatment, which would evaluate addiction treatment outcomes with the goal of increasing effectiveness.

Sources: Prepared by CRS based on congressional budget justification documents and the HHS *Budget in Brief*, available at <http://www.hhs.gov/budget/>.

Notes: Individual amounts may not add to subtotals or totals due to rounding.

^a Amounts may change during the year due to transfers, reprogramming, or other adjustments.

^b For the FY2015, FY2016, and FY2017 request amounts, SAMHSA's FY2017 budget request indicates that the figures have been comparably adjusted to reflect (1) the proposed transfer of one program (the Behavioral Health Workforce Education and Training Program) from SAMHSA to HRSA in FY2017, and (2) a proposed single appropriation for a program (the Minority Fellowship Program) that is currently funded through multiple SAMHSA centers.

APPENDIX A. COMMUNITY HEALTH CENTER FUND

ACA Section 10503 established a Community Health Center Fund (CHCF) to provide supplemental funding for community and other health centers and the National Health Service Corps (NHSC). The law provided annual appropriations to the CHCF totaling \$11 billion over the five-year period FY2011 through FY2015. Of that total, \$9.5 billion was for health center operations and the remaining \$1.5 billion was for the NHSC.

The Medicare Access and CHIP Reauthorization Act of 2015 (MACRA)⁷⁷ appropriated two more years of funding to the CHCF. For both FY2016 and FY2017, MACRA provided \$3.6 billion for health center operations and \$310 million for the NHSC.

CHCF funding has partially supplanted discretionary funding for the health center program and entirely replaced discretionary funding for the NHSC (see Table 7).

Table A-1 shows the amounts appropriated to the CHCF for each fiscal year as well as the post-sequestration levels for FY2013-FY2015. As discussed earlier in this report, the FY2016 CHCF funding was not subject to sequestration. CHCF funds are awarded to the various types of health centers that are supported by the federal health center program. Those include community health centers and migrant health centers, as well as facilities that serve the homeless and residents of public housing. Sequestration of CHCF funding for community health centers and migrant health centers is capped at 2%, whereas CHCF funding for the other types of facilities (i.e., health centers for the homeless and for public housing residents) and for the NHSC is fully sequestrable at the applicable rate for nonexempt nondefense mandatory spending (see Table 2).

Table A-1. Community Health Center Fund, FY2011-FY2017
(millions of dollars, by fiscal year)

Program	2011	2012	2013	2014	2015	2016	2017	Total
Health Center Program	1,000	1,200	1,500	2,200	3,600	3,600	3,600	16,700
<i>Post-sequestration (non-add)</i>	—	—	(1,465)	(2,145)	(3,509)	—	(3,510)	
National Health Service Corps	290	295	300	305	310	310	310	2,120
<i>Post-sequestration (non-add)</i>	—	—	(285)	(283)	(287)	—	(289)	
Total	1,290	1,495	1,800	2,505	3,910	3,910	3,910	18,820

Sources: Prepared by CRS based on ACA Section 10503, MACRA Section 221, and the HHS *Budget in Brief* (FY2015-FY2017), available at <http://www.hhs.gov/budget/>.

Notes: The ACA also included a one-time appropriation of \$1.5 billion for health center construction and renovation. Those funds are separate from the CHCF and are not included in this table.

APPENDIX B. PREVENTION AND PUBLIC HEALTH FUND (PPHF)

ACA Section 4002 established the Prevention and Public Health Fund (PPHF), to be administered by the HHS Secretary, and provided it with a *permanent annual appropriation*. Under the ACA as originally enacted, PPHF's annual appropriation would increase from \$500 million for FY2010 to \$2 billion for FY2015 and each subsequent fiscal year. However, the Middle Class Tax Relief and Job Creation Act of 2012 amended the ACA by reducing the PPHF appropriation from FY2013 through FY2021 as part of a package of offsets to help cover the costs of the law.⁷⁸ The PPHF annual appropriation is now \$1 billion through FY2017, and thereafter will increase in increments to \$2 billion for FY2022 and each subsequent fiscal year.

The HHS Secretary is instructed to transfer amounts from the PPHF to agencies for prevention, wellness, and public health activities. The funds are available to the Secretary at the beginning of each fiscal year. The Administration's annual budget sets out the intended distribution and use of PPHF funds for that fiscal year. The Secretary determined the

distribution of PPHF funds for FY2010 through FY2013. For FY2014 through FY2016, provisions in appropriations acts explicitly directed the distribution of PPHF funds, prohibiting the Secretary from making further transfers.⁷⁹

As discussed earlier in the report, the PPHF appropriation is fully sequestrable at the applicable percentage rate for nonexempt nondefense mandatory spending (see Table 2). Sequestration is applied to the entire appropriation by the Secretary before funds are transferred to the agencies.

**Table B-1. PPHF transfers to HHS agencies
(millions of dollars, by fiscal year)**

Agency	2010	2011	2012	2013	2014	2015	2016	2017 Proposal ^a
ACL	0	0	20	9	28	28	28	28
AHRQ	6	12	12	6	7	0	0	0
CDC	192	611	809	463	831	886	892	944
CMS	0	0	0	454 ^b	0	0	0	0

OS	12	19	30	0	0	0	0	0
SAMHSA	20	88	92	15	62	12	12	28
Sequester	—	—	—	51	72	73	68	—
Total	500	750	1,000	1,000	1,000	1,000	1,000	1,000

Sources: Prepared by CRS from HHS agency congressional budget justifications, <http://www.hhs.gov/budget/>; HHS, “Prevention and Public Health Fund,” funding distribution tables, <http://www.hhs.gov/open/recordsandreports/prevention/index.html>; and Prevention and Public Health Fund transfer tables in explanatory statements accompanying appropriations for FY2014 through FY2016.

Notes: Individual amounts may not add to totals due to rounding. ACL is the Administration for Community Living; OS is the Office of the HHS Secretary.

^a Distribution proposed by the Administration. This is not a budget request, as PPHF funds have already been appropriated. Amounts do not reflect the 6.9% sequestration (i.e., \$69 million) for FY2017 required under current law; see Table 2.

^b Funds were used for implementation of insurance exchanges under the ACA. CMS, *Justification of Estimates for Appropriations Committees, Fiscal Year 2015*, p. 349, <http://www.hhs.gov/budget/>.

The distribution of PPHF funds to HHS agencies for FY2010 through the FY2017 President’s budget proposal is presented in Table B-1. Further details regarding PPHF distributions to CDC and SAMHSA are provided in the respective agency budget tables in the body of this report.

For FY2013, the Secretary transferred almost half of available PPHF funds to CMS for ACA implementation, as shown in Table B-1. This transfer reduced the PPHF funds that had been initially allocated to CDC and other PHS agencies. Along with the sequestration of discretionary⁸⁰ funding in FY2013, the loss of PPHF funds that year had a significant effect on CDC’s budget.

In determining the transfer of PPHF funds for FY2010 through FY2013, the Secretary funded a mix of pre-existing programs and activities, and programs and activities newly authorized under the ACA. In directing the distribution of FY2014, FY2015, and FY2016 PPHF funds, annual appropriations acts (and accompanying report language) in most cases funded pre-existing programs and activities. In some cases the PPHF contribution for FY2016 made up more than 50% of a program’s total funding. Examples include CDC immunization grants to states (54%) and tobacco prevention activities (60%). The CDC Preventive Health

and Health Services Block Grant and the lead poisoning prevention program received 100% of their FY2016 funding from the PPHF.

APPENDIX C. PATIENT-CENTERED OUTCOMES RESEARCH TRUST FUND

ACA Section 6301(e) established the Patient-Centered Outcomes Research Trust Fund (PCORTF) to support comparative clinical effectiveness research at both HHS and the Patient-Centered Outcomes Research Institute (PCORI).⁸¹ The law provided annual funding to the PCORTF over the period FY2010-FY2019 from the following three sources: (1) annual appropriations; (2) fees on health insurance and self-insured plans; and (3) transfers from the Medicare Part A and Part B trust funds.

Specifically, the ACA appropriated the following amounts to the PCORTF: (1) \$10 million for FY2010; (2) \$50 million for FY2011; and (3) \$150 million for each of FY2012 through FY2019. In addition, for each of FY2013 through FY2019, the ACA appropriated an amount equivalent to the net revenues from a new fee that the law imposes on health insurance policies and self-insured plans. For policy/plan years ending during FY2013, the fee equals \$1 multiplied by the number of covered lives. For policy/plan years ending during each subsequent fiscal year through FY2019, the fee equals \$2 multiplied by the number of covered lives. Finally, transfers to PCORTF from the Medicare Part A and Part B trust funds are calculated by multiplying the average number of individuals entitled to benefits under Medicare Part A, or enrolled in Medicare Part B, by \$1 (for FY2013) or by \$2 (for each of FY2014 through FY2019).

For each of FY2011 through FY2019, the ACA requires 80% of the PCORTF funds to be made available to PCORI, and the remaining 20% of funds to be transferred to the HHS Secretary for carrying out PHSA Section 937.⁸² Of the total amount transferred to HHS, 80% is to be distributed to AHRQ. Table C-1 shows the allocation of PCORTF funds through FY2017.

**Table C-1. Distribution of PCORTF funding
(millions of dollars, by fiscal year)**

Funding Recipient	2011	2012	2013	2014	2015	2016 Est.	2017 Est.

APPENDIX D. FDA USER FEE AUTHORIZATIONS

**Table D-1. FDA user fee authorizations and revenue
(millions of dollars, in order of fy2016 anticipated revenue)**

User Fee	Initial Authorizing Legislation and Year	FY2016 Revenue
Prescription drug	Prescription Drug User Fee Act (PDUFA), 1992(P.L. 102-300)	851
Tobacco product	Family Smoking Prevention and Tobacco Control Act, 2009 (P.L. 111-31)	599
Generic drug	Food and Drug Administration Safety and Innovation Act (FDASIA), 2012(P.L. 112-144)	318
Medical device	Medical Device User Fee and Modernization Act (MDUFMA), 2002(P.L. 107-250)	138
Animal drug	Animal Drug User Fee Act (ADUFA), 2003(P.L. 108-130)	23
Biosimilars	Food and Drug Administration Safety and Innovation Act (FDASIA), 2012 (P.L. 112-144)	22
Mammography	Mammography Quality Standards Act (MQSA), 1992(P.L. 102-539)	20
Animal generic drug	Animal Generic Drug User Fee Act (AGDUFA), 2008 (P.L. 110-316)	10
Color certification	Color Additive Amendments of 1960(P.L. 86-618)	9
Rare pediatric disease priority review voucher	Prescription Drug User Fee Amendments of 2012(P.L. 112-144)	8
Food reinspection	Food Safety Modernization Act (FSMA), 2011 (P.L. 111-353)	6
Voluntary qualified importer (VQIP)	Food Safety Modernization Act (FSMA), 2011(P.L. 111-353)	5
Export certification	FDA Export Reform and Enhancement Act of 1996 [for medical products](P.L. 104-134); Food Safety Modernization Act (FSMA), 2011 [for foods](P.L. 111-353)	5
Food recall	Food Safety Modernization Act (FSMA), 2011 (P.L. 111-353)	1
Outsourcing facility	Drug Quality and Security Act (DQSA), 2013(P.L. 113-54)	1
Third party auditor program	Medical Device User Fee and Modernization Act (MDUFMA), 2002 (P.L. 107-250)	1
Tropical disease priority review voucher	Food and Drug Administration Amendments Act (FDAAA), 2007(P.L. 110-85)	0
Total		2,017

END NOTES

¹ HHS also includes three human services agencies that are not part of the Public Health Service: (1) the Administration for Children and Families (ACF); (2) the Administration for Community Living (ACL), which was created in April 2012 by consolidating the Administration on Aging (AoA), the HHS Office on Disability, and ACF's Administration on Developmental Disability; and (3) the Centers for Medicare & Medicaid Services (CMS). Departmental leadership is provided by the Office of the Secretary (OS), which is comprised of various staff divisions including the Assistant Secretary for Preparedness and Response (ASPR), the Assistant Secretary for Health (ASH), the Office of the Surgeon General, the Office for Civil Rights (OCR), the Office of Inspector General (OIG), and the Office of the National Coordinator for Health Information Technology (ONC). For more information on HHS and links to the PHS agency websites, see <http://www.hhs.gov/>.

⁴ SSA Title V, 42 U.S.C. §§701 et seq.

⁵ 25 U.S.C. §§1601 et seq.

⁶ 42 U.S.C. §9604(i).

⁷ Budget authority is the authority provided in federal law to incur financial obligations that will result in expenditures, or outlays, of federal funds. Such obligations include contracts for the purchase of supplies and services, liabilities for salaries and wages, and grant awards. Appropriations are the most common form of budget authority. Discretionary budget authority represents funding that is provided in and controlled by the annual appropriations acts.

⁸ For an overview of each of these three appropriations acts, see CRS Report R44287, Labor, Health and Human Services, and Education: FY2016 Appropriations; CRS Report R44061, Interior, Environment, and Related Agencies: FY2016 Appropriations; and CRS Report R44240, Agriculture and Related Agencies: FY2016 Appropriations.

⁹ The HHS Secretary's FY2016 transfer authority was provided in Section 205 of the FY2016 LHHS appropriations act (P.L. 114-113, Division H).

¹⁰ The ACA was signed into law on March 23, 2010 (P.L. 111-148, 124 Stat. 119). On March 30, 2010, the President signed the Health Care and Education Reconciliation Act (HCERA; P.L. 111-152, 124 Stat. 1029), which included several new health reform provisions and amended numerous provisions in the ACA. Several subsequently enacted bills made additional changes to selected ACA provisions. All references to the ACA in this report refer collectively to the law and to the changes made by HCERA and subsequent legislation.

¹¹ For more discussion of ACA implementation funding, see CRS Report R43066, Federal Funding for Health Insurance Exchanges.

¹² Since FY2014, annual appropriations acts have included a provision instructing the HHS Secretary to use the PHS set-aside funds for the "evaluation ... and the implementation and effectiveness" of programs funded in the HHS title of the LHHS appropriations act. Previously such provisions had restricted tap funds to the "evaluation ... of the implementation and effectiveness" of programs authorized under the PHSA [emphasis added]. The current provision can be found in P.L. 114-113, Division H, Section 205.

¹³ P.L. 114-113, Division H, Section 204.

¹⁴ Only funds appropriated for activities and programs authorized by the PHSA are subject to an assessment. Thus, most of the funds appropriated for CDC, HRSA, NIH, and SAMHSA are assessed. The annual LHHS appropriations act excludes some funding from the set-aside; still other funding is excluded by convention. For example, funds appropriated for HHS block grants targeting prevention, substance abuse, and mental health as well as funds for program management activities and for buildings and facilities are typically excluded from the set-aside. Funding for agencies (e.g., ATSDR, FDA, IHS) and programs (e.g., HRSA's maternal and child health block grant) that are not authorized by the PHSA are also excluded.

¹⁵ For more information see CRS Report R44136, The Agency for Healthcare Research and Quality (AHRQ) Budget: Fact Sheet.

¹⁶ Mandatory spending, also known as direct spending, refers to outlays from budget authority that is provided in laws other than annual appropriations acts. Mandatory spending includes spending on entitlement programs.

¹⁷ For a complete list and discussion of all the appropriations in the ACA, including details of the obligation of these funds, see CRS Report R41301, Appropriations and Fund Transfers in the Affordable Care Act (ACA).

Chapter 507

ARE CURRENT WASTEWATER TREATMENTS ENOUGH TO AVOID PUBLIC HEALTH PROBLEMS IN TUNISIA

ABSTRACT

The reuse of treated wastewater in irrigation and to refill the aquifer became a common strategy in Tunisia to palliate the lack of water resources. However, sewage treatment processes currently used are only partially effective to remove viruses and consequently discharge of contaminated treated wastewater is a potential source of viral infections. Hepatitis A virus (HAV), hepatitis E virus (HEV), norovirus (NoV), rotavirus (RV), enterovirus (EV), astrovirus (AsV), sapovirus (SaV), adenovirus (AdV) and aichi virus (AiV) are, among enteric viruses, the major waterborne pathogens, predominantly transmitted via the faecal-oral route, and important agents implicated in gastroenteritis or hepatitis outbreaks. They are released in large quantities in raw wastewater and can survive for long periods in several environments which present an important public health hazards. Due to their persistence and low infectious dose, enteric viruses can easily infect people via water or food. Although Tunisia is considered as an endemic country for enteric viruses, routine surveillance of viral wastewater quality is not performed and data on viral epidemiology are limited. In this review we provide an overview on the prevalence of the most common enteric viruses in wastewater from different regions of Tunisia including socioeconomic data and seasonal distribution when available. Indeed, efficiency of different wastewater treatment processes for viral reduction is discussed in order to evaluate the risk associated to the wastewater in the country. Data show that RV, HAV, EV and NoV are constantly present in both raw and treated wastewater with high

* Corresponding Author's Email: jesus.romalde@usc.es.

prevalence. Differences in the incidence of these viruses in wastewater within the country are linked to variations in socioeconomic and sanitary conditions, geographic area and climate. We describe also the genetic diversity of multiple pathogenic enteric viruses in sewage. Different viral reduction rates are observed demonstrating the difficulty of the present biological treatments to provide virus-free wastewater effluents. This review contributes to the understanding of the epidemiology of enteric viruses in Tunisia and underlines the need of an environmental surveillance program and official viral controls for treated wastewater. Therefore, efforts should focus on the enhancing of sewage treatment technologies to avoid a social and public health hazard.

Keywords: wastewater, enteric viruses, treatment, prevalence, STP

INTRODUCTION

Because of their arid and semi-arid climate, the Middle East and North Africa (MENA) region has only 1% of global freshwater resources (Qadir et al., 2007). The countries of the MENA depend mainly on seasonal rainfall, have very few rivers and often rely on aquifers, which some of them are non-renewable (Qadir et al., 2010). Consequently, their economies are much more sensitive to the way that water is extracted, transported and consumed than are the economies of other regions (Jagannathan et al., 2009). In addition, with the constant increasing demand of water in different sectors including agriculture, which is the main consumer of water, some of these countries are suffering from hydraulic stress and are threatened by water scarcity (Allan, 2001). Hence, most of MENA countries had established processes of integrated water resource management, which advocated new approaches for the assessment, management, and development of freshwater resources. Among these strategies, the increase of treated wastewater reuse rates, in both agriculture and industry, has been proposed as the best alternative to preserve as long as possible natural water resources in the driest part of the world (Bahri, 2008).

Tunisia is a country of MENA region, located in the extreme north of Africa, and influenced by three types of climate: Mediterranean climate in the north, semi-arid climate in the central part and desertic climate in the south. Thus, the annual rainfall is on average of 594 mm in the North, 289 mm in the Centre and only 156 mm in the extreme South (Neubert and Benabdallah, 2003). This situation made Tunisia a country with relatively limited renewable water resources, having unequalled geographical distribution. Faced to the continuous increase in water demand, due to the rapid population growth coupled with industrialization, urbanization and agricultural intensification, the country recognizes a constant drop in the availability of water resources.

As economy of Tunisia is mainly based on agriculture, irrigation consumes about 83% of the total volume of distributed water. Therefore, according to the National Sanitation Office (ONAS), a treated wastewater reuse program in agriculture, irrigation of green spaces and aquifer recharge, has been launched from the early 1980s in order to preserve water resources. However, irrigation with treated wastewater back to the year 1965 with the first perimeter of the Soukra irrigated with treated wastewater from the treatment plant of Chargaia. Thanks to initiatives taken by the State, since 1989, to encourage the use of this source and to minimize its release in the aquatic environment (Bahri and Brissaud, 1996), the policy of treated

wastewater reuse was enhanced and irrigated areas have undergone significant evolution.). The increase in wastewater production, mainly due to the urban population growth as well as the increase of public sewer connection rate, raised subsequently the annual productive reuse of treated wastewater in agriculture, reaching 120 million m³ in 1996 and 210 million m³ in 2010 (Ministère de l'Agriculture de Tunisie, 1998). From 2015, 28% of these waters (60 million m³) are reused for irrigation of 8150 hectares of agricultural areas, including citrus fruits, olives, peaches, pears, apples, pomegranates, grain and industrial crops, 1040 hectares of golf courses and 450 hectares of green spaces.

However, regulations regarding the discharge and reuse of wastewater were implemented by the Tunisian Republic (Journal Officiel de la République Tunisienne, 2010):

- Decree n° 85-86 (02-01-1985) regulates wastewater discharges in the receiving environment by setting the terms for their release from wastewater treatment plants (STPs). This decree stipulates that treated wastewater must meet the criteria established by the standard NT 106.02, approved in July 20, 1989 (INNORPI, 1989a), which regulates the discharge conditions and defines the quality of effluents according to the receiving environment (sea, lakes, rivers...). In fact, reduction values required for wastewater discharges are evaluated according to physicochemical parameters, including biochemical oxygen demand (BOD), chemical oxygen demand (COD), total suspended solids (TSS) and total phosphorus and nitrogen, bacteriological parameters, several heavy metals and some organic micro-pollutants.
- Decree n° 93-2447 (13-12-1993) specifies modalities of treated wastewater reuse in agriculture by limiting the use for only crops irrigation except vegetables, whether eaten raw or cooked (Bahri and Brissaud, 1996). It sets also the frequency of analysis for physicochemical parameters (once a month), trace elements (once every six months), and bacteriological analysis for the research of helminth eggs (once every two weeks). To be reused, treated wastewater quality must follow the standard NT106.03, approved in June 1989 (INNORPI, 1989b), which supervises the reuse of treated wastewater in agriculture in order to avoid a negative impact on public health.

Despite all the efforts made by the State to improve the quality of treated wastewater, there is neither regulation or survey program for viruses. In addition, reduced values of various parameters do not address indication of behaviour of highly stable pathogens (like viruses), and current methods of wastewater treatment are not very effective against them, which subsequently cause viral contamination of the environment. The lack of virological analysis and the inability to provide virus-free treated wastewater constitute a potential hazard to public health since the government is investigating, through pilot projects, the reuse of treated wastewater for aquifers recharge, irrigation of forests and highways, as well as for industrial use.

STPs represent the main reservoir and a spreading mechanism of all kinds of pollutants and a large variety of enteric viruses transported by urban wastewater, especially in cases of sewage system dysfunction. Tunisia was the first among Mediterranean countries to use STPs, implemented initially in big cities in order to protect citizens' health and promote their living, then on coastal areas, wetlands, small and medium communities and industrial areas. Actually, most STPs are located along the coast to protect water resources and fragile

ecosystems and to improve the quality of bathing water of coastal resorts (Bahri and Brissaud, 1996).

Many wastewater treatment processes were therefore developed and employed prior to discharge wastewater into the natural environment. The process starts with primary elimination of the bulky waste by screening, followed by secondary biological or physicochemical treatment and completed with tertiary treatment to refine the final quality of treated wastewater. Actually, Tunisia utilises both primary and biological secondary treatment processes in almost all STPs (Qadir et al., 2010). A range of biological wastewater treatment options is used, including activated sludge and lagoon processes, but treatment level varies between urban and rural areas (Qadir et al., 2010). However, with the increase in urban population, some STPs do not have the capacity to process such large volumes and consequently, retention times for wastewater become too short to be effective. Therefore, the government efforts are currently focused on the upgrade to tertiary level treatment (Melhem et al., 2014).

Human sewage can contain a wide variety of different viruses, routinely introduced in the environment through the discharge of raw and treated wastewater. The most important human pathogenic viruses are enterically transmitted and able to cause a wide spectrum of illnesses. They are transmitted primarily via faecal-oral route, either by direct contact from person to person or indirectly through consumption of contaminated water or food, being the origin of many epidemics in developing countries. However, other modes of transmission, such as sexual, parenteral and zoonosis, can be also considered. Enteric viruses are very small microorganisms, about 25 to 220 nm, non enveloped and thus very stable in the environment (Bosch et al., 2008). As obligate intracellular parasites, these viruses are unable to multiply outside the cell host and remain inert for a long period until they are ingested by accident. Once replicated, they are shed in very high numbers in the faeces of infected persons, up to 10^{11} viral particles per gram of stool, reaching then wastewater treatment plants before to be released in the environment. In water, they are preferentially adsorbed to settleable suspended solids (clay, sand, sediment) that protect them against environmental stressors, allowing their concentration in sediments and preserving their infectivity. Due to their great resistance to physical and chemical agents, their low infectious dose, their high concentrations in faeces (Patel et al., 2009), enteric viruses can, through the discharge of wastewater, easily contaminate soil, water and food.

Enteric viruses are classified into three main groups according to pathologies they produce in humans. The first group includes mainly norovirus (NoV), rotavirus (RV), sapovirus (SV), adenovirus (AdV), astroviruses (AsV) and aichi virus (AiV), causing acute gastroenteritis. The second group includes hepatitis A virus (HAV) and hepatitis E virus (HEV) that are responsible of acute enterically transmitted hepatitis. Enteroviruses (EV), members of the third group, can migrate to other organs after replication in the intestinal tract, causing lesions of the central nervous system, gastrointestinal tract infections, respiratory infections, mucocutaneous infections and conjunctivitis (Koopmans and Duizer, 2004).

In Tunisia, little is known about prevalence of these viruses in wastewater and only major pathogenic agents, such as HAV, HEV, NoV, RV, EV and AiV were studied.

HEPATITIS A VIRUS

Hepatitis A virus (HAV) is the only representative of the genus *Hepatovirus* in the family *Picornaviridae* and the etiological agent of acute hepatitis A (Bosch et al., 2008; Lu et al., 2004). It is a linear single-stranded ribonucleic acid virus (RNA), non-enveloped with approximately 7.5 kb genome, protected within an icosahedral capsid (Pintó et al., 2012). HAV has been classified into six genotypes (I to VI) (Costa-Mattioli et al., 2002; Lu et al., 2004; Cristina and Costa-Mattioli, 2007) and a single serotype (Sanchez et al., 2002; Hollinger and Emerson, 2007; Perez-Sautu et al., 2011). The first three genotypes (I, II and III), subdivided into two subtypes A and B (Byun et al., 2001), were isolated from humans while the other three (IV, V and VI) were isolated only from simian species who developed a hepatitis A-like disease (Nainan et al., 1991; Tsarev et al., 1991).

HAV is more resistant in the water environment than other picornavirus: It is found in tap water after 60 days (Enriquez et al., 1995) and in the sterile mineral water after 89 days (Debord and Buisson, 1998). It can also survive for up to 8 weeks in groundwater (Sobsey et al., 1989), over 6 weeks in the river waters (Springthorpe et al., 1993), and up to 30 weeks in sea water (Crance et al., 1998).

Waterborne transmission of HAV may occur in different ways, either by consumption of contaminated water (Kukkula et al., 1997) or during recreational activities (Fleisher et al., 1996). Since HAV is excreted in faeces in a large number of copies (up to 10^{11} copies/g of faeces) (Costafreda et al., 2006; Pinto et al., 2012), transmission is facilitated by poor sanitation (Jacobsen and Koopman, 2005). Furthermore, the use of contaminated wastewater in irrigation of green areas or in agriculture may also be the origin of several cases of hepatitis A (Koopmans and Duizer, 2004; Bosch et al., 2008). In addition, their release in seawater presents a potential risk to public health, given that the virus is concentrated by filter-feeder organisms such as mussels and oysters and their consumption, either raw or undercooked, is associated sometimes in the appearance of large scale epidemics (Costafreda et al., 2006; Pintó et al., 2009; Rodríguez-Lázaro et al., 2012). Secondly, food washed with contaminated water and eaten raw may constitute a source of infection.

In Tunisia, hepatitis A remains endemic, with high/intermediate ranking (Letaief et al., 2005; Rezig et al., 2008; Gharbi-Khelifi et al., 2007; Melhem et al., 2014; Ouardani et al., 2015), occurring primarily in young children at high rates. HAV serologic studies conducted in the 2000s in different regions, depending on age, have shown high prevalence, in young children aged under 10 years (44% - 84%) as well as children aged from 10 to 15 years (59% - 91%) and teens aged from 16 to 25 years (83% - 92%). The prevalence of infection varies between urban and rural areas, according to the development of regions, hygienic conditions and sewage facilities (Letaief et al., 2005; Rezig et al., 2008). However, in many urban areas, hepatitis incidence has not been reduced although the improvement of hygiene conditions in those areas. As hepatitis A disease may be symptomatic or not, detectable HAV in wastewater would provide an important overview of its spread in the general population (Ouardani et al., 2015). Several reports, conducted in the country on raw and treated wastewater samples, showed high HAV rates ranging between 46% and 68.3% and high HAV loads up to 1.68×10^9 genome copies(GC)/L, suggesting the important role of this source of viruses in the transmission of the disease (Gharbi-Khelifi et al., 2007; Béji-Hamza et al., 2014; Ouardani et al., 2015, 2016).

Despite of the potential public health hazard linked to the lack of good sanitation and the use of contaminated treated sewage, few studies have been carried out in Tunisia on the seasonal and geographical distribution of HAV in the environment. In these reports, analysis of the epidemiological pattern of HAV infection, taking into account the socio-economic and sanitary conditions, geographic localisation and climate, showed that viral rate detected in West-central Tunisia is slightly higher (62.96% to 69.2%) than in East-central (50.62% to 65.7%) (Ouardani et al., 2015, 2016). Analysis of the seasonal distribution of HAV in wastewater, conducted in different parts of Tunisia, have shown that HAV circulates throughout the year with certain seasonal variation. In these studies, highest viral rates were found during summer (67.07%) in coastal areas and during winter (85.4%) and autumn (80%) in West-central regions (Ouardani et al., 2015, 2016), suggesting that geographic localisation and climate may play an important role on the seasonal variation of HAV circulation. These differences would certainly be related to the proximity of these areas to the coast and the consequent condensation of tourism population, mainly from neighbouring countries such as Algeria and Libya, but also from European Union. Quantitative data showed high HAV rates during summer (10^9 GC/L) which might suggest the occurrence of outbreaks in this period (Ouardani et al., 2015, 2016).

Phylogenetic studies of HAV conducted in Tunisia from wastewater samples showed the predominance of the sub-genotype IA over several years with the presence of some strains closely related to European strains demonstrating the circulation of this sub-genotype variant in the Mediterranean region (Chironna et al., 2003). However, the sub-genotype IB remains infrequent in the country (Gharbi-Khelifi et al., 2006; Béji-Hamza et al., 2014; Ouardani et al., 2015, 2016) and was described in the coastal regions, especially in touristic areas, with high number detected during spring and summer (Ouardani et al., 2016). These facts suggest that this sub-genotype, circulating in Europe, may be imported by travellers during Easter or summer holidays vacation.

HEPATITIS E VIRUS

Hepatitis E virus (HEV) is the etiologic agent of enterically transmitted non-A, non-B hepatitis in humans worldwide (Emerson and Purcell, 2003) classified as a member of the genus *Orthohepevirus*, species *Orthohepevirus A*, within the family *Hepeviridae* (Khuroo and Khuroo, 2016; Smith et al., 2016). As for HAV only one serotype has been described for HEV but four major genotypes have been identified based on nucleotide sequencing. Genotypes 1 and 2, restricted to humans, have been found in Asia, Africa and North America, while genotypes 3 and 4 are zoonotic and can infect both humans and animals such as domestic pigs, wild boars, and other mammals (Li et al., 2005; Feagins et al., 2008). The genotype 3 is frequently found in the world whereas the genotype 4 has been found only in Asia. HEV is a positive single-stranded RNA nonenveloped virus. The genome is approximately 7.2 kb in length containing short 5' and 3' noncoding regions (UTR) and three open reading frames (ORFs 1, 2 and 3) (Wang et al., 2000; Huang et al., 2007). The virus is resistant to high temperatures at 56°C for 1 h but it is sensible to boiling, frying and chlorination (Emerson et al., 2005; Khuroo and Khuroo, 2016). HEV is primarily transmitted by the fecal-oral route (Emerson and Purcell, 2003; Phan et al., 2005) and epidemics are

usually linked to contaminated water, occurring only in developing countries of Asia, Africa and in Mexico (Meng, 2010). In these countries, outbreaks of HEV infections are closely linked to poor hygienic conditions and consumption of uncontrolled water (Masclaux et al., 2013; Garcia et al., 2014).

In Tunisia, very few studies were conducted on HEV in wastewater and its prevalence remains not well known. Unlike high prevalence reported in other North African countries (Kamal et al., 2010) as well as some developing areas, where levels in wastewater reached 40.7% in Pakistan (Ahmad et al., 2010) and 55.6% in India (Vivek et al., 2013), HEV seems to be infrequent in our country with viral contamination of 2% in wastewater (Béji-Hamza et al., 2015). This result is in line with seroprevalence studies that showed low rates (4.3% - 6.8%) of HEV in Tunisian population (healthy invidious and blood donors) (Rezig et al., 2008; Houcine et al., 2012; Ben-Ayed et al., 2015). Phylogenetic analysis, conducted by Béji-Hamza and co-workers, showed the presence of genotypes 1 and 3 in environmental samples, suggesting the circulation of these two genotypes in the Tunisian population (Béji-Hamza et al., 2015).

NOROVIRUS

Norovirus (NoV) represents the most important cause of infectious human gastroenteritis (Patel et al., 2009) and food-borne outbreaks of acute gastroenteritis worldwide (Green, 2007; Patel et al., 2008, 2009). It is a non-enveloped icosahedral virus with positive single-stranded RNA of 7.5-7.7 kb. NoVs are classified within the family *Caliciviridae*, and subdivided into five genogroups (GI–GV) (Karst et al., 2003; Zheng et al., 2006) and several serotypes. Genogroups I, II and rarely IV are known to infect humans (Green et al., 1994; Wang et al., 1994; Ando et al., 2000; Zheng et al., 2006; Patel et al., 2009) whereas GIII affects swine. Based on VP1 coding sequence analysis, more than 33 different genotypes were described within NoVs genogroups (Zheng et al., 2006; Zheng et al., 2010), with genotype II.4 being the most common cause of gastroenteritis outbreaks (Siebenga et al., 2009; Zheng et al., 2010).

Little is known about NoV occurrence in wastewater in Tunisia, and the only two studies found in the literature were carried out in the coastal region of Monastir using small samples number. Data showed a variation on the prevalence of this virus from 4.4% to 67.6% (Hassine et al., 2010; Sdiri-Loulizi et al., 2010; Hassine-Zaafrane et al., 2014), being detected during winter and spring with high rates in the months of February and May (Hassine et al., 2010). These results are one line with other reports described by Melnick (1991) and Lopman et al. (2004), demonstrating a seasonal pattern of NoV during the cold season with occasional appearance of epidemics observed especially during spring. Phylogenetic studies showed high frequency of GI NoV in the environment (Hassine-Zaafrane et al., 2014; Hmaied et al., 2015) contrary to clinical samples where GII were predominant (Hassine-Zaafrane et al. 2013). No clear explanation for this discrepancy was found but authors suggested the possibility of infection by various genotypes of NoV with GI strains might be more resistant in wastewater and less severe or lead to asymptomatic infections compared to GII (Duizer et al., 2004; Rzeżutka and Cook, 2004; da Silva et al., 2007).

ROTAVIRUS

Rotavirus (RV) is the principal cause of severe diarrhea in children below 5 years of age, with approximatively 140 million cases and 453,000 deaths described in developing countries each year (Steele et al., 2003; Tate et al., 2012). Group A rotavirus (RV-A) is associated with a large majority of severe gastroenteritis, in both humans and animals, occurring in developed and developing countries and represents the major cause of child mortality (Parashar et al., 2006; Sanchez-Padilla et al., 2009). RV-A is a nonenveloped icosahedral virus of 70 nm in diameter, containing 11 segments of a double-stranded RNA genome of approximately 18.5 kb (Okoh et al., 2010; Rodríguez-Lázaro et al., 2012). It is classified within *Reoviridae* family, genus *Rotavirus*, and divided into G and P genotypes. At least 27 G types and 37 P types of RV-A have been identified to date (Matthijssens et al., 2011; Trojnar et al., 2013), of which G1-G4, G9, G12, P4 and P8 are most commonly found infecting humans (Gentsch et al., 1996; Martella et al., 2010).

Like the other enteric viruses, RV persist in the water environment (Hurst and Gerba, 1980) and its inactivation in different types of water was correlated with higher temperatures (John and Rose, 2005). Prevalence of RV-A in wastewater were determined in only some region of the East-Central Tunisia, being detected in 72.4% of wastewater samples with viral rates of 76.1% and 68.7% in raw and treated wastewater, respectively. However, variation on RV-A prevalence between STPs (from 70.8% to 81.4%) was associated to the origin of influents where domestic wastewater may contain greater quantities of virus than industrial water (Hassine-Zaafrane et al., 2015). Seasonality of RV-A was also studied and showed high prevalence during winter (28.5%) and spring (32.8%). In addition, high viral loads were observed in December, March and July which corresponded to school holidays when high influx of invidious from other regions were noted (Hellmér et al. 2014; Hassine-Zaafrane et al., 2015).

Molecular genotyping of RV-A wastewater samples in Tunisia showed a great diversity of genotypes with the presence of 10 G types and 8 P types (Hassine-Zaafrane et al., 2015). Most of them belonged to G1-G4, G9, P[4], P[6], P[8] and P[9] and described as being epidemiologically relevant for humans, while some detected genotypes as G6, G8, G10, P[1], P[5], P[11] and G5, G11, P[7] have been commonly found in bovine and swine, respectively (Papp et al. 2013; Hassine-Zaafrane et al., 2015).

ENTEROVIRUSES

Enteroviruses (Evs) are the viruses most commonly encountered in humans and infections by these viruses have been estimated at 1 billion worldwide (Palacios and Oberste, 2005). EV consists of spherical nonenveloped virus, with a positive single stranded RNA genome of 7.2–8.5 kb, belonged to the genus *Enterovirus* within the family *Picornaviridae* (Stanway et al., 2005). Actually, more than 100 serotypes of enteroviruses, ratified by the Executive Committee of the International Committee on Taxonomy of Viruses (ICTV) (Lauber and Gorbalenya, 2012; Adams et al., 2013), are distributed in four species in humans (A, B, C and D): EV-A contains some coxsackievirus A strains; EV-B includes coxsackievirus A9, coxsackievirus B1-6 and most of the echoviruses; EV-C comprises

polioviruses 1–3 and some coxsackievirus A strains (Stanway et al., 2005). EV68 and EV70 are the two serotypes found in the EV-D species (Smura et al., 2007). EVs can replicate in the respiratory tract and the gut and are transmitted by respiratory or faecal–oral route (Rodríguez-Lázaro et al., 2012). Although most of infections are asymptomatic, EVs can be responsible for a wide spectrum of diseases in humans, including acute paralytic poliomyelitis, aseptic meningitis, encephalitis, myocarditis, pericarditis and conjunctivitis. They are also involved in respiratory system infections and gastroenteritis as well as insulin-dependent diabetes (Wagenknecht et al., 1991; Kocwa-Haluch, 2001; Griffin et al., 2003).

EVs are highly resistant in several environments and able to preserve their infectivity for months (Wetz et al., 2004; Fong and Lipp, 2005; Rajtar et al., 2008), which reflects their widespread occurrence in populations (Sellwood et al., 1981; Hovi et al., 1996; Sedmark et al., 2003). As other enteric viruses, they can contaminate soil, food crops and natural watercourses through the discharge of contaminated wastewater. In Tunisia, the presence of EV in wastewater was also documented and most studies showed high prevalence from 30.2% to 50% (Sdiri et al., 2006; Hassine et al., 2010; Ibrahim et al., 2014). Hassine and co-workers (2010) showed, through monitoring of EVs seasonality in wastewater, a regular circulation of these viruses throughout the year (except in the months of November, February and March) with predominance during summer and autumn. It has been described that in the Mediterranean climate, EVs are endemic with possibility of outbreaks appearance during summer-autumn (Nairn and Clements, 1999; Belghuith et al., 2004). Furthermore, molecular characterization of EVs from wastewater samples has shown the circulation of the three species A, B and C in the country (Ibrahim et al., 2014).

AICHIVIRUS

Aichi virus (AiV) is a causative agent of gastroenteritis in humans, transmitted like all enteric viruses by faecal-oral route (Ambert-Balay et al., 2008). It is classified as a member of the Aichivirus species, genus *Kobuvirus* within the family *Picornaviridae* (Knowles et al., 2012). The virus is nonenveloped with an icosahedral nucleocapsid of 30 nm in diameter which protects a positive single-stranded RNA of approximately 8.3 kb in length coding for a single open reading frame (ORF) (Burutarán et al., 2016). Based on their nucleotide sequences similarity (Yamashita et al., 2000; Yamashita and Sakae, 2003; Ambert-Balay et al., 2008), AiV was divided into three genetically distinct genotypes, where genotypes A and B are more frequent than the genotype C (Ambert-Balay et al., 2008; Kaikkonen et al., 2010; Jonsson et al., 2012). Since its first identification in 1989 in Japan (Yamashita et al., 1991), AiV was isolated in several countries of Asia (Pham et al., 2007), Europe (Oh et al., 2006; Ambert-Balay et al., 2008), South America (Oh et al., 2006), at low prevalence from children suffering from gastroenteritis. To date, there are only two reports that described the occurrence of AiV in Tunisia, and showed higher viral rate of 4.1% in stool samples isolated from children (Sdiri-Loulizi et al., 2009), compared to other countries such as France (0.9%), and 6% in wastewater samples collected from several STPs located in the East-Central of the country. These results confirm that AiV present in wastewater may reflect virus circulation in the community and suggest that it is an emergent virus implicated in gastroenteritis. Moreover, it has been reported that genotype A of AiV was predominant in Tunisia, in both

clinical and environmental samples, as well as in Europe and Asia (Oh et al., 2006; Ambert-Balay et al., 2008, Yamashita et al., 2000). Indeed, phylogenetic analysis showed that nucleotide sequences of the environmental strains were closely related to those found in clinical samples, suggesting a parallel evolution of the environmental and clinical strains over time.

EVALUATION OF BIOLOGICAL WASTEWATER TREATMENT PROCESSES USED IN TUNISIAN STPs

Waterborne transmission represents one of principal modes of indirect transmission of enteric viruses to humans and is the origin of many epidemics in developing countries (Ali et al., 2004; Bosch et al., 2005). Thus, great resistance of these viruses in water environment, inadequate wastewater treatment processes and reuse constitute a potential risk on public health since they are shed in high quantities in the faeces and subsequently can contaminate fresh products such as vegetables, salads, fruits and filter-feeding molluscs (Okoh et al., 2010; Bosch et al., 2009). These latter are able to concentrate viruses by filtration, through their gills, of large quantities of sea water (100 to 650 liters/ hour/kg of mussels) and their consumption, even raw or lightly cooked, presents a high risk of enteric virus carriage (Croci et al. 2007; Gabrieli et al. 2007).

Therefore, since wastewater represents the main source of enteric viruses (Rodríguez-Lázaro et al., 2012), the effectiveness of processes used to the treatment for viral removal should be assessed before wastewater reuse in irrigation and other sectors or release in the nature (Hmaied et al., 2015). There has been increasing concern about the evaluation of wastewater treatment processes efficiency to avoid viral environmental contamination and to develop new strategies to remove viruses. However, several studies were conducted in this field and showed an inefficiency of most of the current wastewater treatment processes to remove viruses with reduction rates vary from 20 to 80% (Payment et al., 1986; La Rosa et al., 2010; Prado et al., 2011; Ouardani et al., 2015). Therefore, as released viruses are able to preserve their infectivity for a long period, they can easily contaminate diverse food items (Masclaux et al., 2013) and environmental waters such as lakes, rivers, sea, and drinking water resources.

As described previously, Tunisia is one of many developing countries that developed its secondary sewage treatment plants (Melhem et al., 2014) in order to reuse treated wastewater in several sectors, mainly in agriculture, to palliate the lack of water resources (Jebri et al., 2012). It has been reported that the government is investigating the reuse of these waters to refill the aquifers, forests irrigation and in industry through pilot projects. However, quality of treated wastewater remains poor (El Ayni et al., 2013) and the lack of specific surveillance program for enteric viruses in wastewaters (Sdiri-Loulizi et al., 2010) could, among many risk factors (Jacobsen and Koopman, 2005; Rodríguez-Lázaro et al., 2012; Melhem et al., 2014; La Rosa et al., 2014), increase public health risk related to the viral contamination in wastewater. Indeed, given that Tunisia is ranked between countries highly endemic for almost enteric viruses causing hepatitis and gastroenteritis, transmission of infections may be facilitated with poor hygiene conditions and inappropriate wastewater reuse.

Little is known about the efficiency of wastewater treatment processes currently used in Tunisia to remove enteric viruses. Therefore, in several studies viruses have been detected in treated wastewater and it has been confirmed that whatever the method used by STP, it is impossible to provide virus-free wastewater (Hassine-Zaafraane et al., 2014; Hmaied et al., 2015; Ouadani et al., 2015, 2016). Tunisian urban wastewater is a mixture of human sewage, suspended solids, debris and a variety of chemical substances that originate from residential, commercial and industrial activities (Okoh et al., 2010). To ensure the depuration of these waters, STPs are using both primary and secondary treatment processes where a range of wastewater treatment options is used and treatment level varies between urban and rural areas (Qadir et al., 2010). Unfortunately, due to the rapid increase in urban population and high use of water during summer, some STPs do not have the capacity to process large volumes of wastewater and consequently retention times for wastewater treatment become too short to be effective.

Based on data provided by ONAS, the majority of Tunisian STPs are using to the depuration of urban wastewater biological secondary treatments, of which activated sludge and lagoon are the most widespread in the country (Qadir et al., 2010; Melhem et al., 2014; Ouadani et al., 2015). Within activated sludge process, we distinguish three methods as follow: conventional activated sludge (medium charge) used for large community, extended aeration activated sludge (low charge) and extended aeration oxidation ditch activated sludge (low charge) used for medium to small community. However, two varieties of lagoon processes exist, natural/ facultative lagoon and aerated lagoon, and they are used only for the treatment of small volume of wastewater. Currently, Tunisian efforts are focused on the upgrade to tertiary level treatment (Melhem et al., 2014). All these processes lead to remove pollutants, both chemical and biological, from wastewater before discharge to the environment and although they are not intended to eliminate viruses, the effectiveness of viral reduction would probably be improved (DeBusk, 1999; Okoh et al., 2010).

Data on the prevalence of enteric viruses in treated wastewater in Tunisia were provided in several reports and showed low viral reduction. For HAV, regardless the wastewater treatment process, removal rate reached 39.1% (Ouadani et al., 2016) which corresponded to viral reduction found in other reports (20-80%) (Payment et al., 1986; La Rosa et al., 2010; Prado et al., 2011; Ouadani et al., 2015). indeed, values in outflows (22.7%-40.7%) were slightly lower than in inflows (56.8%-66.9%). High viral concentration were also noted in treated wastewater samples collected from many STPs and ranged from 3.9×10^3 to 1.4×10^8 GC/L (Ouadani et al., 2015, 2016). Activated sludge process is widely used by cities and communities where large volumes of sewage should be treated in a cost-saving manner. The comparison of the three activated sludge processes showed a complete failure of conventional activated sludge (medium charge) with 63.6% of positive samples being detected in treated wastewater samples and viral reduction rate of 7.9% (Ouadani et al., 2016). Extended aeration and oxidation ditch activated sludge processes (low charge), used to overcome some of limitations associated with the conventional activated sludge (Benjes, 1976), had high/moderate efficiency against HAV varying from 32.4% to 91.47% (Ouadani et al., 2015, 2016). However, lagoon process seems to be better to remove HAV since Ouadani and co-workers showed a removal rates of 71.8% to 100% and viral load reduction was more than 1 log unit (Ouadani et al., 2015).

Other studies focused on molecular detection of NoV in effluents, treated by conventional activated sludge process, showing viral rates of 47.9% (Hassine-Zaafraane et al.,

2014). NoV GI (83.3%-96.4%) was more prevalent than NoV GII (2%-66.6%) with viral concentrations ranged from 2.72×10^2 to 2.6×10^3 GC/L for GI and from 33 to 175 GC/L for GII (Hassine-Zafrane et al., 2014; Hmaied et al., 2015). Furthermore, RV was detected in 68.7% (Hassine-Zafrane et al., 2015) of treated wastewater samples with high concentrations ranged from 5.2×10^5 to 1.3×10^7 GC/L (Hassine-Zafrane et al., 2015; Hmaied et al., 2015).

These findings demonstrate the high resistance of these viruses to all kind of wastewater treatments and point to a potential health risk if final effluents are discharged into fresh or marine water systems or reused in irrigation. This low efficiency to eliminate viruses depends generally on origin of influents, viral type, wastewater pH, the nature of the suspended solid (Arraj et al., 2005), environmental conditions and wastewater treatment level (Hmaied et al., 2015). Otherwise, it has been reported that several factors may affect the efficiency and the reliability of the treatment process, such as hydraulic and organic overloads of the STP, equipment and structures very old and deteriorated, lack of operating staff and the entering of industrial wastewaters (Ouardani et al., 2016). According to a study, conducted in a variety of STPs and introducing the latter parameter on the evaluation of treatment efficiency, has shown lowest virus removal rate in STPs collecting large volume of industrial wastewaters with higher viral loads in treated wastewater than those found in raw sewage. These findings were partially explained by the fact that industrial raw wastewater contains high loads of both organic and chemical pollutants as well as heavy metals that may inhibit the PCR (Sobsey and Hickey, 1985; Tsai and Olson, 1992).

CONCLUSION

The study and assessment of enteric viruses in Tunisian wastewaters may provide an insight on viral circulation in general population, their resistance to wastewater treatment processes and to estimate the public health risks associated with these viruses. Moreover, evaluation of secondary biological wastewater treatment processes commonly used in Tunisia has important implications on the development of official controls and the establishment of viral indicators, in order to improve the microbiological control of treated wastewater, especially that this renewable source is reused for many activities, mainly in agriculture. As an example, investigations performed up to now indicate that the replacement of conventional activated sludge treatments and the establishment of tertiary treatments seems to be necessary to reduce as much as possible viral contamination of the environment.

These measures together with an improvement of hygienic practices through educational programs would be of great help to reduce and/or avoid public health problems related with enteric viruses in Tunisia.

ABSTRACT

Water is an essential resource to all living beings. Ensuring good quality of drinking water is a basic factor in guaranteeing public health, the protection of the environment and sustainable development. Several studies have revealed that the chemical and microbiological qualities of ground and spring waters are in violation of acceptable standards, and may not conform to National Standards as expected by the consumers. Water can become contaminated by a number of ways, such as naturally occurring chemicals and minerals, the lack of or malfunctioning sanitary infrastructures, or land practices. The major microbiological risk associated with water is its fecal contamination, which can be a source of pathogenic bacteria, viruses or parasites; its most common indicators are the presence of coliforms such as *Escherichia coli*, intestinal enterococci or *Clostridium perfringens*. These microorganisms have been implicated as the source of several intestinal diseases, urinary tract infections, neonatal meningitis, gastroenteritis, typhoid fever and cholera. Chemical pollution, the other type of water contamination, can be organic or inorganic. Organic chemicals include leachate [e.g., from solid waste], synthetic organic compounds, and chlorinated compounds like trihalomethanes [THM], which are associated with poisoning, cancer, liver, kidney and central nervous system problems. Inorganic compounds, on the other hand, consist of substances resulting from water treatment and pesticides or pollution resulting from industry [e.g., Cd, Ba, Hg, Mo and B]. Many diseases are associated with these elements including poisoning, cancer,

* Corresponding Author's Email: luisfarmacognosia@gmail.com.

hypertension and infantile cyanosis. Thus, it is essential to control water quality regularly, focusing primarily on physicochemical and microbiological aspects. The aim of this chapter will be to perform a microbiological and physicochemical characterization of ground and spring waters associated with public health issues.

Keywords: ground water, spring water, microbiological analysis, physicochemical composition, public health

INTRODUCTION

Water is an essential resource to all living beings [1]. Therefore, it is of major importance not only to have an adequate and accessible supply, but also to have quality water that is considered safe to human consumption [1, 2]. This is crucial to assure public health, but it is also essential to environmental protection and sustainable development assurance [3].

Potable water can be divided into three groups: groundwater, springwater and the remaining forms of water suitable for human consumption. Both ground and spring waters are originated from underground, but the former is mainly characterized by its stable physicochemical characteristics, and its high content on mineral salts and oligoelements which result from its interaction with the existing underground rocks. These characteristics can bring several human health benefits [4, 5].

Water can become contaminated by a number of ways, such as naturally occurring chemicals and minerals [6], the lack of or malfunctioning sanitary infrastructures, or land practices [6, 7]. The major microbiological risk associated with water is its fecal contamination, which can be a source of pathogenic bacteria, viruses or parasites; its most common indicators are the presence of coliforms such as *Escherichia coli* [EC], intestinal enterococci [IE] or *Clostridium perfringens* [CP] [1, 8, 9].

In terms of physicochemical aspects, as water is an excellent solvent, it might contain several chemical substances that can be a hazard to human health over prolonged consumption [1, 9]. These parameters are easily changeable, especially in underground water, due to climatic and hydrogeological conditions, water flow velocity, composition of the formations, among others [2]. Chemical substances can be organic or inorganic [8]. Inorganic substances constitute by far the greatest proportion of chemical contaminants in drinking water. They can appear as a consequence of natural processes but mostly they appear from contaminants as a result of Man's activities. Inorganic contaminants are also the most important for water consumer's acceptability, affecting water's taste and color, and causing scale deposition on pipes and fittings. They have an important impact on health as well, having both beneficial and adverse effects which have been shown in human populations. Several health problems, such as poisoning, cancer, hypertension, liver, kidney and central nervous system diseases, and infantile cyanosis can be attributed to these contaminants [8, 10].

Thus, it is essential to regularly control water quality, focusing primarily on physicochemical and microbiological aspects.

In this chapter we will describe some of the most important physicochemical and microbiological parameters to be determined in drinking-waters.

PHYSICOCHEMICAL CHARACTERISTICS

Physicochemical properties are important for the water's organoleptic characteristics and their modification can cause health problems for consumers.

pH

The water pH is the negative logarithm of the molar hydrogen activity: $\text{pH} = -\log[\text{H}^+]$. It is a measure of the acid-base equilibrium and is controlled by the carbon dioxide-bicarbonate-carbonate equilibrium system in most cases [10]. The European legislation applied to consumption water has stated its legal limits (6.5-9.5) [11]. Slightly lower levels than the limits generally don't compromise groundwater quality in terms of human consumption, as they only reflect the geological composition of the grounds [4, 7].

Generally, the pH doesn't affect consumers directly, as there is no health-base guideline value proposed for this parameter, although extreme values of pH may result in irritation of the eyes, mucous membranes and skin [10]. Nonetheless, it is still a crucial parameter in water quality: for instance, pH of waters in distribution networks should be especially monitored, as low levels of pH may lead to corrosion of the metal pipes used, and to a subsequent chemical contamination. In addition, water pH is also important to the efficiency of treatment processes, as levels of pH below 8 may reduce chlorination's effects [10].

Electrical Conductivity and Total Dissolved Solids

Total Dissolved Solids (TDS) represents the amount of inorganic salts [calcium, magnesium, sodium, potassium, carbonate, chloride, sulfate, nitrate, among others] and organic matter present in the water [1].

TDS affects water's organoleptic properties, mainly its palatability, and therefore can even affect its acceptability for consumption. Taste panels have rated the palatability of water and classified it into five categories, presented in Table 1. However, water with very low mineral content can also be considered insipid and flat [10].

There are no health-base guideline values for TDS as the levels found in drinking-water are not of health concern [1].

Table 1. Influence of TDS in water palatability [10]

Category	TDS level (mg/L)
Excellent	<300
Good	300-600
Fair	600-900
Poor	900-1,200
Unusable	>1,200

In summary, this relevance of this parameter is mainly associated with organoleptic properties and it is as well a very broad indicator of chemical contaminants.

TDS is determined most commonly through the measurement of Electrical Conductivity (EC), although it can also be determined gravimetrically, and through the individual measurement of ions [4].

EC is the numeric expression of the capability of a solution to carry an electric current, and it is dependent on the concentration, mobility and valence of the present ions. Therefore, it is dependent on several factors such as the mineral composition of the grounds [11, 12]: granite grounds, as they are mainly composed of particles that don't ionize when in contact with water, are not good electrical conductors, as opposed for example of limestone grounds because of the dissolution of its carbonate minerals [12]. Also, EC has proven to be useful in determining the extent of the influence of run-off and effluent discharges in aquatic systems [13]: discharges of wastewater from a damaged sewage system should raise EC, as a result of its chloride, phosphate and nitrate composition, in contrast to oil discharges [12]. On the other hand, organic compounds don't have much influence on EC as they are not very good electrical conductors [12].

Turbidity

Turbidity is a major physical characteristic of water and therefore it belongs to the National Primary Drinking Water Regulations (NPDWR) of EPA [14]. The NPDWR are legally enforceable standards to public water systems, which are meant to protect the public against consumption of health threatening contaminants [14].

This characteristic is a measure of the cloudiness of water and it is caused by the presence of suspended or colloidal matter, which can be either organic, inorganic or both, that favors the scattering and absorption of light by particles and molecules, rather than its transmission [1, 11]. This parameter, expressed in Nephelometric Units (NTU), is determined using instruments that detect the amount of light scattered by a sample at a specific angle. This nephelometric method is calibrated using suspended formazin standards [15, 16].

In drinking water the most common sources of turbidity are: water discharges, algae, organic compounds resulting from decay of plants or decomposing animals, silt, clay, high levels of iron, and particles from water treatment [16, 17].

High levels of turbidity are not only aesthetically unappealing but they also may indicate possible microbial contamination, as the present matter can provide attachment and shelter to microorganisms (preventing proper water disinfection and increasing the risk of gastroenteritis), heavy metals, pesticides or toxic organic compounds [16].

The levels of turbidity should be 1 NTU and preferably much lower, although higher levels (up to 5 NTU) could be acceptable in groundwater if the turbidity is not of health concern (in the absence of bacteria, levels of nitrate-nitrogen inferior than 1 mg/L, construction of well is acceptable, and no evidence of other kind of contamination is present) [16].

It is highly recommended that waters with high turbidity are subjected to coagulation, sedimentation and filtration (prior to disinfection) in order to be considered microbiologically safe to drink [1].

Hardness

Total Hardness (TH) represents the water dissolved calcium and magnesium salts due to water contact with ground rocks [11] and is a measure of the capacity of water to react with soap [1].

It is composed by both temporary hardness (carbonate and bicarbonate, which might be eliminated by water boiling) and permanent hardness (noncarbonate, such as chloride, nitrate and sulphate, which are not susceptible to water boiling) [1, 11].

Table 2. Classification of waters according to TH [1]

Water Category	Quality	Hardness (mg/L)
Very soft	Good	0-60
Soft		60-150
Moderately hard	Medium	150-300
Hard	Acceptable	300-600
	Hard to soften	>600

Water is classified as “hard” when it has very high levels of these salts and is classified as “soft” when it has low levels. Table 2 show the classification and quality of water according to its hardness. Water from limestone areas is harder than water from granite areas [1].

In terms of health-based limits, there are none established as this parameter is not considered of health concern [1, 18, 19]. However, hardness levels also affect the consumer as water with hardness values lower than 100 mg/L might have low buffering properties and lead to the possibility of pipes’ corrosion and, on the other hand, hardness higher than 200 mg/L can also lead to an excessive need of soap to produce foam [1, 11], precipitation of soap scum and accumulation on tubs and showers, presence of white deposits more noticeable on glassware, and also a reduction of efficiency of water heating devices [1, 20].

Trihalomethanes

Trihalomethanes (THMs) are a group of four chlorinated chemicals [chloroform, bromoform, bromodichloromethane, dibromochloromethane] first identified in the 1970s that form in drinking-water as a result of the chlorination of the organic matter (such as algae and decaying leaves) present in water [1, 21]. Chloroform is generally the most commonly detected THM.

Although these chemicals are tasteless and odorless, they are harmful and potentially toxic, and are therefore Total THMs (TTHMs) are one of the parameters included in the NPDWR of EPA [21].

The chemical formulas and guideline values of the THMs are present in Table 3.

As THMs are volatile chemicals they are transferred to the air. Therefore, there are four main routes of exposure: ingestion of drinking-water, inhalation of indoor air, inhalation and dermal exposure during showering, bathing or ingestion of food [21].

Table 3. Chemical formulas and guideline values of THMs [1, 21]

Trihalomethane	Chemical formula	Guideline values (mg/L)
Trichloromethane [chloroform]	CHCl_3	0.3
Tribromomethane [bromoform]	CHBr_3	0.1
Dibromochloromethane	CHClBr_2	0.1
Bromodichloromethane	CHCl_2Br	0.06
Total Trihalomethanes	-	0.08

The exposure to THMs is not generally associated with acute effects, but to chronic effects, such as increased risk of cancer and liver, kidney and central nervous system problems. In terms of cancer, chloroform and bromodichloromethane are classified as possibly carcinogenic to humans (group 2B) as they were found to be carcinogenic in animal studies; bromoform and chlorodibromomethane are not classified concerning their carcinogenicity [21].

THMs can be reduced by reducing the organic material before chlorination of the water, optimization of chlorine usage, changing the point of chlorine addition in the treatment series and use alternative disinfection methods [22].

Metals

Drinking water can be a good source of essential (such as Ca, Mg, Fe and Zn) but also of nonessential heavy metals or metalloids (As, Pb, Tl, U, B) which are considered toxic to the human health [23].

Heavy metals are naturally occurring elements but they might also be present in water due anthropogenic activities, such as mining, smelting operations and industrial production. Water contamination with these metals might also result from metal corrosion, atmospheric deposition, among others [24].

Ingestion of these metals might lead to their accumulation causing several health problems, mainly in the central nervous system [specially in children], and in the reproductive system [23].

Among drinking waters, the metals with relatively high concentrations and therefore of special concern are As, Cd, Pb, Cr, Cu, and Hg [25]. Inorganic As is classified as a human carcinogen and is associated with skin damage and circulatory problems. It may be present in waters due to erosion of natural deposits and runoff from wastes [14, 25, 26]. Cd is also classified as a human carcinogen and is related with kidney damage. Its presence may be due to corrosion of pipes, discharge from metal refineries and also runoff from waste batteries and paints [14, 25]. Inorganic Hg is also associated with liver and kidney damage [14, 25]. Pb is related with the development of anemia, learning deficits, kidney damage and high blood pressure [14, 25]. Cr might be present in drinking water due to discharges from mills as well as erosion of natural deposits, and its presence is related to allergic dermatitis [14, 25]. Cu is associated with gastrointestinal symptoms and the development of Wilson's disease [14, 25].

MICROBIOLOGICAL ANALYSIS

One of the major problems in water potability is the microbiological contamination [1], mostly associated with fecal contamination from wastewater or landfills [8].

This problem is predominantly present in developing countries, such as African countries, where the mortality associated with waterborne diseases is superior to 5 million people per year, and half of these are intestinal infections [27, 28]. Also, water has the potential to disseminate microbial agents to a large number of individuals, and, in the presence of pathogens, to cause illnesses [27].

Contaminated water can lead to several health problems, from mild gastritis, to dysentery or typhoid fever, and can also be the source of disease outbreaks [1]. Diarrheal diseases account for 80% of all water related diseases and are responsible for 1.5 million deaths every year, mostly in children under five in African and Asian countries [29, 30]. In Europe, an average of 330.000 cases of water related diseases are reported every year, including typhoid fever, enterohemorrhagic EC infection, viral hepatitis A, giardiasis, or cholera [30]. Also, in the United States of America these diseases are reported to cause 12.000 death per year [30]. Hence, microbiological evaluation is essential to guarantee safe water, and it should be systematic.

Total Microorganisms

Total microorganisms count represents the water's general bacterial content [31], having little sanitary importance [1], and can be useful in monitoring treatment and disinfection processes and evaluate the cleanliness and integrity of distribution systems [31, 32]. For this reason, further studies need to be performed to evaluate the presence of fecal contamination indicators.

Total Coliforms and *Escherichia coli*

Total Coliforms is a bacteria group that belongs to the family Enterobacteriaceae and is composed of a great variety of Gram negative bacilli that grow in the presence of high concentrations of bile salts and ferment lactose [1]. Some of the most commonly genera found in water are *Escherichia*, *Citrobacter*, *Enterobacter*, *Klebsiella*, *Serratia* and *Yersinia* [33]. This group includes both fecal and environmental species [34]; therefore is also not a good indicator of fecal contamination, but its presence is a sign of inadequate treatment and disinfection [1].

If a water sample is positive for coliform bacteria is useful to determine the species of coliform to determine the significance of the contamination and potential source [34].

EC is the most adequate indicator of fecal pollution, occurring in human and animal feces, sewage and recently contaminated water and soil [1]. Hence, it can also be used as an indicator of water treatment effectiveness [31].

This species is part of the normal bacterial intestinal flora, and most strains are nonpathogenic. There are, however, certain pathogenic strains.

EC isolated from intestinal illnesses has been divided into six groups: enteropathogenic *E. coli* (EPEC), enterohemorrhagic *E. coli* (EHEC), enterotoxigenic *E. coli* (ETEC), enteroinvasive *E. coli* (EIEC), enteroaggregative *E. coli* (EAEC) and diffusely adherent *E. coli* (DAEC) [35, 36]. We will give special relevance to the ETEC, EHEC and EIEC groups.

ETEC infections are associated with infantile gastroenteritis in developing countries, and are also the most common cause of traveler's diarrhea [35, 36]. These microorganisms lead to the illness through two enterotoxins (one thermo-resistant and the other thermo-labile) that ultimately affect electrolyte transport leading to fluid loss [36, 37]. The infectious dose of microorganisms is 10^6 which leads to profuse diarrhea for several days [27].

EHEC produce Shiga-like toxins (toxins similar to those produced by *Shigella dysenteriae*) and are mostly associated with the consumption of raw or undercooked food [35, 37]. The infection has an incubation period of 3-8 days (4 days on average) and the illness has a duration of 1-12 days (4 days on average) [37]. An infection with <100 organisms of the most prevalent serotype O157:H7 causes abdominal pain and watery and bloody diarrhea. In more severe cases, the infection may also lead to Hemolytic Uremic Syndrome (HUS). In the more recent years, other serotype, O104:H4, was implicated in a great outbreak in German, with 3842 cases of gastroenteritis and 855 of HUS, with a total of 53 deaths [38].

The EIEC group contains bacteria capable of invading the intestinal epithelial cells, leading to abdominal cramps, diarrhea, among other symptoms [27, 35, 36]. The infectious dose of these microorganisms is 10^6 - 10^{10} and the illness is similar to *Shigella* dysentery.

Besides intestinal infections, *E. coli* is one of the most frequent agent of urinary tract infections [36], and an increasingly common cause of meningitis and sepsis [35].

Intestinal Enterococci

IE are Gram-positive cocci, catalase negative, oxidase negative and antigen Lancefield's group D [33]. These microorganisms are also specific for fecal pollution, although these have some differences in comparison to EC, such as being more resistant to chlorination and the capability to live longer in water [1]. Some of the most common IE to be present in water are *Enterococcus faecalis*, *E. faecium* and *E. durans* [39].

Fecal bacteria can have a negative effect in Human health, as they can lead to gastrointestinal illnesses, generally mild, but of major concern in immunocompromised individuals [39].

In case of IE positivity, it is necessary to investigate the possible sources/causes of contamination, such as inadequate water treatment, location near to a source of contamination, or lack of treatment, among others [1].

Clostridium perfringens

Clostridium are Gram-positive anaerobic rod-shaped bacteria. CP, a sulphite-reducing clostridia, is an accurate indicator of fecal contamination as well. This species produces resistant spores that are very resistant to a number of unfavorable environmental conditions and water treatments (such as ultra-violet irradiation and chlorine disinfection) [31], and,

therefore, it is used to indicate contamination that took place previously, rather than recent contamination (such as the TC, EC, or IE) [1]. CP is removed by coagulation and flocculation and, as its spores are very small, its presence can be an indicator of problems in the filtration processes [1, 31].

The consumption of CP contaminated water can lead to one of two forms of illnesses. The most common is the gastroenteritis form, a mild form, characterized by cramps and watery diarrhea, which, in most cases, goes away by itself the day after (except in immunocompromised, or in the case of a violent strain). The other, but very rare disease is called “pig-bel disease,” a type of necrotizing enteritis, which is often fatal. Nevertheless, these diseases only occur when large numbers of CP are present in the water [40].

Salmonella

Salmonella are motile Gram-negative bacilli, non-spore forming, that belong to the Enterobacteriaceae family, and are characterized by their O, H, and Vi antigens. This genus is composed only of two species: *S. enterica* and *S. bongori* [37]. *S. enterica* is subdivided in six subspecies: enterica [the one that is most associated with human infections, including the typhoid and paratyphoid bacilli], salamae, arizonae, diarizonae, indica and houtenae [41]. Furthermore, *Salmonella* is also divided in two serovars according to the caused clinical syndromes: the typhoidal and non-typhoidal serovars [41].

The clinical syndromes caused by infection with *Salmonella* are divided into three groups: gastroenteritis, enteric fever and septicemia [41]. Gastroenteritis is self-limiting and occurs up to two days after ingestion, depending on the dose of bacteria ingested. It is characterized by nausea, vomiting, diarrhea, fever and abdominal pain, and usually resolves after a few days [37]. Enteric fever is a multisystemic potentially fatal disease caused mainly by *S. typhi* and *paratyphi*. The *S. typhi* caused syndrome has an incubation period of 10 to 14 days, and symptoms are non-specific, including fever, diarrhea, abdominal pain, myalgias. Antibiotics should be promptly administrated, otherwise the infection may be fatal [37]. Lastly, *Salmonella* septicemia might be an intermediate stage without intestinal symptoms when the bacteria is not isolated in fecal samples [37].

CONCLUSION

Water is essential to the survival of all beings, and therefore it is crucial to assure its quality. The parameters to be evaluated are divided into physicochemical and microbiological. The physicochemical parameters include the pH, total dissolved solids, electrical conductivity, turbidity and hardness; the microbiological parameters include the total microorganism count, and the evaluation of the presence and count of total coliforms, *E. coli*, intestinal enterococci, and *C. perfringens*. As the alterations in these parameters might indicate water alterations or contamination and may turn it unsuitable for drinking, it is fundamental to determine these parameters in drinking waters.

INTRODUCTION

Physical activity is important for a healthy lifestyle and for example parks can provide opportunities for physical activity for both children and adults in their neighborhood [1]. A study in 20 neighborhood parks in Durham, North Carolina with 2,712 children and adolescents showed that the type of activity area and presence of other active children were positively associated with physical activity, while the presence of a parent was negatively associated [1]. Results showed that physical activity of girls was more strongly affected by social effects (like other active children) whereas physical activity of boys was more strongly influenced by the availability of park facilities [1].

A study from Finland of 37,699 adults looked at childhood adverse psychosocial factors and adult neighborhood disadvantage to understand if there was a link to increased cardiovascular disease [2]. They found that combined exposure to high childhood adversity and high adult disadvantage was associated with cardiovascular disease risk factors (hypertension, dyslipidaemia, diabetes, obesity, smoking, heavy alcohol use and physical inactivity), while exposure to high childhood adversity or high adult neighborhood disadvantage alone was not significantly associated with cardiovascular disease [2].

* Corresponding Author's Email: jmerrick@zahav.net.il.

Another study with 1,842 adults from Brazil looked at the local retail food environment and consumption of fruits and vegetables and sugar-sweetened beverages [3]. They found that availability in neighbourhoods was associated with regular fruits and vegetables consumption, but regular fruits and vegetables consumption prevalence was significantly lower among lower-income individuals living in neighbourhoods with fewer supermarkets and fresh produce markets. A greater variety of sugar-sweetened beverages was associated with a 15% increase in regular SSB consumption.

A recent [4] study used data from the Multi-Ethnic Study of Atherosclerosis (MESA), which involve more than 6,000 men and women from six communities in the United States (New York, Baltimore, Chicago, Los Angeles, Twin Cities and Winston Salem) to look at how neighborhood environments may influence the risk for developing type 2 diabetes mellitus (T2DM). They wanted to investigate long-term exposures to neighborhood physical and social environments, availability of healthy food and physical activity resources and levels of social cohesion and safety in relationship to T2DM. During a follow-up period of about ten years of adults aged 45-84 years at baseline 616 out of 5,124 participants (12.0%) developed T2DM and the study found a lower risk for developing T2DM associated with greater cumulative exposure to indicators of neighborhood healthy food and physical activity resources [4].

The studies above are just examples of recent research interest into the interrelation between neighborhood and the effects on health [5]. This relationship is complex and also very hard to research, since it is multidisciplinary and multi agency with different community development policies, urban planning, zoning and transportation policies involved.

In order to better understand the role of these environments and identify the most effective interventions in order to improve health will require partnerships between researchers, the neighborhood communities and policy makers.

Chapter 510

PUBLIC HEALTH ASPECTS OF SUICIDE IN CHILDREN AND ADOLESCENTS

Ahsan Nazeer*, MD

Department of Psychiatry, Western Michigan University,
Homer Stryker MD School of Medicine, Kalamazoo, Michigan, USA

ABSTRACT

Suicide in children and adolescents is a complex and devastating problem for families and society both nationally and internationally. This review considers various aspects of this phenomenon including its epidemiology, risk factors, protective factors, issues of prevention, and management. Risk factors for suicide have been reviewed including personal characteristics, psychopathology of those committing suicide, history of previous suicide attempts, sexual orientation, familial factors, and access to lethal means of suicide. Protective factors include social support and religion. Principles of prevention have been considered including school-based programs, screening tools, skills training, Gatekeeper training, community-based programs, and health-care programs. Management includes principles involved in management before and after self-harm. Also considered are family therapies and therapies aimed at specific problems such as depression, bullying, substance abuse, and others. Clinicians should be actively involved with their communities to seek prevention of suicide in children and adolescents.

Keywords: childhood, adolescence, suicide, public health

INTRODUCTION

Child and adolescent suicide is a complex global public health problem that has intrigued researchers, academicians and policy makers for decades. Suicide is one of the leading causes of death; an estimated 30,000 people in the United States and 1 million people worldwide die

* Corresponding Author's Email: ahsan.nazeer@med.wmich.edu.

of suicide. Global suicide rates have increased drastically, and lost U.S. productivity due to suicide is now estimated at \$12 billion per year. The World Health Organization and United States (US) government have taken numerous steps toward establishing policies and prevention strategies, including calls for expanded collection of suicide data. Suicide also is one of the major causes of death in the adolescent population.

Despite the fact that progress has been made in our understanding of risk factors for suicide, it remains a major global medical burden. Among the 4 million suicide attempts yearly, about 90,000 adolescents succeed, averaging one successful attempt every 5 minutes; the cumulative result is that suicide is the 5th leading cause of adolescent death worldwide. In the following review, we will examine the current research on prevalence, risk factors and prevention strategies.

EPIDEMIOLOGY

The U.S. adolescent suicide rate gradually increased during the 20th century, becoming more marked during the 1960s and reaching an overall peak in the 1990s, although there have been other significant peaks and troughs. Although adolescent suicide rates stabilized during the late 1990s, they had increased by 250% between 1960 and 1980 and doubled between 1960 and 2001. Since the late 1990s, the suicide rate has declined, reaching a 30-year low in 2003 [1]. Numerous explanations for this reduction have been put forth, including earlier identification of at-risk teens, better and more focused delivery of mental health services to families in need and increased use of antidepressants. Unfortunately, this overall epidemiological trend shifted between 2000 and 2005, with a 14% increase in youth suicide during these years. This shift may have been due to reduced antidepressant prescribing amid the public health outcry and “black box” warnings regarding the association of antidepressant use with emergence of suicidal ideation.

The US Centers for Disease Control (CDC) recently published the National Suicide Statistics, with data updated to cover 2009, the latest year for which these numbers are available. According to the CDC, suicide rates declined in both sexes for the 1991-2000-time period but were consistently higher for 2001-2009. The CDC data also identifies numerous disturbing trends, including a 233% increase in suffocation suicide rates among females 10-24 years old. On the other hand, firearm suicide rates in females aged 10 to 24 years decreased from 1993 through 2007, while poisoning remained relatively constant at 0.48 suicides per 100,000 from 2002 to 2009. During 2005-2009, use of a firearm (29.7%) was the preferred mode of suicide among 10-24 year-old males, but suffocation (48.5%) was more common among the equivalent female cohort. For the same group, firearms and suffocations caused the largest number of fatal self-injuries, while poisoning and cutting caused the fewest.

Demographically, group differences between males and females do not exist until mid-to-late adolescence (15-19 years), at which time the rate of suicide among males increases dramatically. During 2005-2009, the highest suicide rates were among American Indian/Alaskan Natives and Non-Hispanic Whites. Suffocation was the preferred method of suicide among American Indian/Alaskan Natives while Non-Hispanic Whites preferred firearms. Asian/Pacific Islanders had the lowest suicide rates among males, while Non-

Hispanic Blacks had the lowest rates among females. In 2009, more female high school students planned (13% vs 8%) and attempted (8% vs 4%) suicide, as compared to their male peers [2].

Global Suicide Rates

Nationally recorded data on child and adolescent suicide must be interpreted with caution, as there are differences in data reporting among different nations. In many cultures, suicide in adolescents is usually under-reported, due to the desire to protect families from the stigma of suicide and to avoid any future social repercussions. Another reason to be cautious in comparing data is that different studies use different questionnaires to assess suicidality; the resultant variability in results may be due to measurement bias. A few recent studies, including the WHO/EURO Multicenter Study on Parasuicide and the WHO Multisite Intervention Study, have used standardized measures to overcome this bias.

Because of the above-mentioned inconsistencies, global figures for teen suicide vary, but it continues to be the 2nd leading cause of death, after motor vehicle accidents (MVA). Worldwide, suicide is the 3rd leading cause of death among adolescent males, after violence and MVA; it is the leading cause of death among adolescent females. Rates are highest in Eastern Europe and the Russian Federation and lowest in Central and South America. The male-to-female ratio continues to range from 3:1 to 7:1, except in India and China, where no differences are found between genders.

Suicide in Young Children

Suicide in children younger than 10 years of age is considered to be a rare phenomenon. Scientific literature has reported suicidal ideation in children as young as 5 years of age; however, this is controversial. Researchers have suggested that depression and substance abuse problems, two major risk factors for suicide in adolescents, are either rare or simply not present in very young children. Others have argued that because young children engage in concrete operational thinking and have limited problem solving abilities, they are not capable of understanding the finality of death and therefore cannot plan for a suicide attempt.

On the other hand, developmental theorists agree that the common denominator in a suicide attempt is *intent* to self-harm, regardless of the child's understanding of causality, finality and lethality of attempt. Parental absence and a family history of suicidal behavior are two factors that are associated with earlier onset of suicidal ideation in children. So far, the most consistent pattern that has emerged from the literature is that the risk of suicide increases significantly at 12 years of age and peaks at 16 years of age. In the U.S., suicide mortality rates were 1.5/100,000 for 10-14 year-olds and 8.2% for 15-19 year-olds [3].

RISK FACTORS

More than 30% of youth who commit suicide have some personality traits in common. In one study, children in the 12-14 year age range who had attempted suicide were frequently described as intelligent, socially isolated, aggressive and vulnerable to criticism. A history of impulsive aggressiveness has consistently been shown to predispose to suicidal behavior. Impulsivity by itself may lead to suicide attempts, as evidenced by the fact that many adolescents with ADHD show little planning before their attempts. Low self-esteem and hopelessness also have been associated with current and future suicidal ideation and attempts. Recent loss, interpersonal conflicts and legal issues are common precipitants for suicide in conduct-disordered youth [4].

Psychopathology

Youth with psychiatric disorders carry a 9-fold increase in suicide risk as compared to their peers. More than 90% of young suicide attempters have at least one diagnosed psychiatric disorder, and increased severity and chronicity of the disorder is strongly correlated with increased suicide risk.

Mood disorders are the most prevalent psychiatric disorders among adolescent suicide victims of both genders. The odds ratio of increased suicide risk ranges between 11 and 27 among those with a mood disorder. Among the mood disorders, depression continues to be a major precipitant for suicide and disability in adolescents. In one study, more than 60% of adolescents with depression had had a history of suicidal ideation, and more than 30% of them had attempted suicide. In 2004, the US Food and Drug Administration (FDA) issued a “black box warning” for antidepressants; a decrease in the use of these medications to treat depression and a subsequent increase in completed suicides followed. Recent meta-analysis suggests that the benefits of treating depression outweigh the risks associated with these medications. Data regarding bipolar disorder and suicide is discrepant, as some studies have indicated that having bipolar disorder is a risk factor for suicide whereas others have not associated it with increased risk [5].

Substance use disorders are highly comorbid with mood disorders and are a major risk factor for suicide in older youth. It also has been noted that the diagnostic profiles of youth with suicide attempt and youth with suicidal ideation are somewhat different and that substance abuse is more closely associated with suicide attempt than with ideation. Other psychiatric disorders, including anxiety, posttraumatic stress disorder (PTSD) and conduct disorder also have been reported to be associated with increased risk of suicide.

Previous Suicide Behaviors

A history of previous suicide attempt is the single most important predictor of subsequent suicidal behavior, while suicidal ideation in the absence of a plan is associated with a decreased risk of suicide attempt in the future. Regarding the course of suicidal ideation, it is

noted that 34% of individuals with suicidal ideation will make a suicide plan and 72% of those with a plan will make a suicide attempt.

The risk of a repeated suicide attempt is highest during the first 3-6 months following the initial attempt, with greater increased risk for male adolescents (30-fold) than for females (3-fold). In comparison to the general population, this risk remains elevated for the next 2 years. Ongoing suicidal intent and the potential lethality of the method used in the previous suicide attempt are other variables that impact the future course of suicidal risk. Youth who make highly lethal attempts and have serious suicidal intent are at extremely high risk for repeated attempts. Serious suicide intent is characterized by: 1) having certain beliefs about the suicide, 2) planning for a successful attempt, 3) taking measures to avoid detection and 4) expressing a wish to die.

Sexual Orientation

Recent research has found a 2-6-fold increase in non-lethal suicidal behaviors among homosexual youth. This risk is aggravated by comorbid depressive symptoms, substance use and a sense of victimization.

Familial Factors

A family history of suicide behaviors is one of the strongest predictors of suicide in youth. There is evidence that suicidal behavior is familial and transmitted irrespective of risk for other psychiatric disorders. Youth suicide is about 5 times more likely among children whose mothers have completed suicide, while first-degree relatives of suicide attempters have a 2-6-fold increased risk of suicidal behavior, compared to the general population.

Parental psychopathology, particularly depression and substance use disorder, has been associated with completed suicide and suicide attempts in youth; however, other studies have failed to find this association after controlling for the youth's psychopathology and psychosocial stressors. Loss of a parent to death or divorce before 12 years of age is a significant risk factor for completed suicide. There is also a consistent body of research linking youth suicide with family discord. Physical and sexual abuse and poor communication with the father are other risk factors for youth suicide attempts.

Access to Lethal Means

There is a consistent body of literature linking the presence of firearms at home with completed suicides. The availability of a gun at home makes it more likely that a gun will be used as a method of suicide. Absence of guns from the home makes it less likely that one will be used for a suicide attempt and may result in the use of less lethal means. There is also an association between stricter gun control laws and lower suicide rates.

PROTECTIVE FACTORS

Protective factors are those that decrease the likelihood of a suicide attempt, despite the presence of psychopathology.

Social Support

Social support, including the perception of family cohesion, is noted to be a protective factor for suicidal behavior. Adolescents who describe family life as emotionally supportive are 3-5 times less likely to engage in suicidal behavior than peers with the same levels of mood psychopathology and life stress. Presence of young children at home is associated with *increased* risk of a *first* onset of suicidal ideation, but in the long-term this factor is protective against suicide.

Religion

Empirical research on the effects of spiritual beliefs and religious practices is in its infancy; however, the protective role of religion against suicidal behavior in African Americans is noteworthy. It has been posited that some of this beneficial effect may be mediated by meeting with like-minded people in religious services, people who can provide support during times of stress.

PREVENTION

Youth suicide prevention strategies are aimed at identifying young people who are at risk of self-harm. Traditionally these measures are implemented in school, community and health-care systems [6].

School-Based Programs

Suicide awareness programs were implemented on the premise that adolescents are more likely to confide in and seek support from their peers than from adults. The objective of these programs was to provide knowledge and to improve help-seeking behaviors in students. During the last two decades, several studies have evaluated these programs but so far have failed to find a positive effect. There is in fact evidence to the contrary, that these curriculum-based suicide awareness programs can cause at-risk students to become more distressed and less likely to seek care. Because of these results, emphasis has shifted from promoting “suicide awareness” to alternative strategies described below.

Screening

One strategy that has received attention is direct case finding via systematic screening. School-wide screening programs use self-report questionnaires and individual interviews and have focused on identifying youth with depression, recent or past suicidal ideation and attempts, and substance use problems. This systematic screening is sensitive (83%-100%) in finding youth at risk, but is less specific (51%-76%). In order to minimize false positive screening results, direct case finding using standardized interviews such as the Diagnostic Interview Schedule for Children (DISC) are employed.

Skills Training

Skills training programs are aimed at strengthening cognitive and behavioral skills, with an emphasis on problem solving and coping skills, to both reduce the impact of suicide risk factors and enhance the effects of protective factors.

School Personnel Training (Gatekeeper Training)

Only one-tenth of high school teachers and one-third of school counselors believe that they can identify a student at risk of suicide. The purpose of this training is to increase knowledge and improve skill among school personnel with regard to identifying students at risk and making referrals when needed. These programs have shown improvement in intervention and referral skills among school personnel and are well accepted by school principals.

Community-Based Programs

Crisis centers and hotlines provide immediate support to youth in crisis. There is limited information about the efficacy of hotlines in the prevention of youth suicide, but about 15% of suicidal teens report having used these hotlines.

Firearms are one of the most common methods of committing suicide. Imposing restrictions on firearms as a means of preventing youth suicide is a key strategy but has shown conflicting results. Some studies have noted reduction in overall suicide rates while others have not found such an effect. While “mean-restricting measures” are a politically volatile topic in the US, providing education to parents of high-risk youth about limiting their access to firearms is less controversial and has been found to be marginally effective.

Healthcare-Based Programs

There is a dire need for pediatricians and primary care physicians to be trained to screen for suicide and mood disorders. In one study, 72% of primary care physician stated that they

have prescribed antidepressants to adolescents, but only 8% stated that they had formal training in the treatment of adolescent depression. Educational programs for health care professionals have shown promise in reducing suicide rates, but ongoing efforts toward enhanced education are warranted.

MANAGEMENT

Despite significant public interest and public health agency concern regarding youth suicide, there is limited data available to support recommending one intervention over another. Unfortunately, it is difficult to predict suicide, but management can be broadly categorized into ‘before self-harm’ and ‘after self-harm’ groups [7].

Management before Self-Harm

In this phase of treatment, identification of at risk youth by screening and adequate treatment or referral is important. Physicians should use routine health care visits to screen for mental illness and suicidal thoughts. Risk factors need to be identified, but caution is advised in interpreting these risk factors, as many commonly occur and do not lead to a suicide attempt in the majority of cases. Common identifiable risk factors are noted in table 1.

Primary care physicians should feel comfortable interviewing depressed teens and estimating their level of distress and the extent of their dangerousness to self and others. Table 2 lists common warning signs for adolescent suicide that should be considered during the evaluation.

The recommended method for assessment of suicidal thoughts is a direct interview of the at-risk youth. It is recommended that confidentiality be discussed, with an explanation that the physician must act in the best interest of the youth if there is a danger to self or others. The adolescent and the parents should be interviewed separately, as important information is likely to be withheld in the parents’ presence. The events preceding the suicidal intent and any self-mutilation behaviors should be assessed in detail. Self-mutilating behaviors are associated with significant psychopathology and should not be dismissed as being attention-seeking or manipulative; this behavior confers a 3-10% lifetime risk of eventual suicide.

Table 1. Common youth suicide risk factors

• Family: Separation, familial discord, impaired parent-child relationship, parental divorce, loss of a parent • Parents: Parental mental health problems • Psychopathology: Mood, psychosis, and sub-stance use disorders, panic disorder, history of aggression and impulsivity • Trauma: History of past physical or sexual abuse • History of previous suicide attempts • Difficulty adjusting to gender identity • Social: Difficulties in school, limited friends, bullying, not attending school, break-up with girlfriend/boyfriend, awareness of a friend’s self-harm
--

Table 2. Warning signs of youth suicide

• Sudden negative change from baseline behavior • Agitation • Intoxication • Recent stressful event • Unprovoked episodes of crying • Indications of youth being in an abusive relationship • Recent onset of apathy and withdrawal • Hopelessness, guilt and feelings of worthlessness • Preoccupation with death • Giving away prized possessions • Worsening signs of depression

Physicians should ask questions to assess known risk factors as well as level of intent. Self-harming behaviors may or may not be associated with a true intent to commit suicide and should be assessed in the context of other risk factors, in order to avoid having a false sense of security. Physicians also should assess protective factors, as listed in Table 3, including the youth’s reasons for living. Individuals who believe that it is acceptable to end one’s life have a 14-fold increase in risk of making a suicide plan. The youth’s access to lethal means, including medications and guns, should be assessed, and parents should be counseled regarding reducing access to such items.

Table 3. Protective factors

• Family cohesiveness • Supportive family environment • Engagement in school activities, including sports • Good academic achievement • Religiosity

If there is any reason to believe that an adolescent is at risk of suicide, the physician or support staff must stay with the individual until a plan is established for providing an appropriate level of care. Although data is lacking, the safest course of action in these situations is to arrange for hospitalization, which provides a safe and supportive environment for the adolescent.

Management after Self-Harm

In the majority of cases, and adolescent who has attempted suicide presents to an emergency room, where a psychiatrist, psychologist or psychiatric nurse assesses them. A thorough psychosocial evaluation, including assessment of protective factors, should be conducted [8]. Collateral information should be taken from parents; however, in more than

80% of cases, the parents are unaware of a suicide attempt. The physician should explore the adolescent’s “concept of death” by asking: “What would you expect to happen?” or “Had you thought you would still be around to see the consequences of an attempt?” Lethality of attempt also should be considered, although it is not a good indicator of suicide intent, as children may not have the cognitive skills necessary to estimate the level of lethality of their attempt. Table 4 lists the characteristics of suicide attempt that suggest high self-harm intent.

Table 4. Characteristics that indicate high suicide intent

• Planned and prepared in advance • Told others beforehand about suicidal thoughts • Timed to avoid discovery by parents • Suicide note or a message left • Others were not informed after the act
--

As noted above, inpatient hospitalization is usually the safest course of action following a teen suicide attempt; however, this decision must be made in conjunction with the available data about the presence or absence of factors that may indicate risk for repeated self-harm.

Table 5. Characteristics that indicate risk for repeated self-harm

• Lack of remorse and constant hopelessness after the failed attempt • History of previous suicide attempts • Family history of completed suicide attempt • Social isolation • Ongoing substance use problems • Psychosis

If the decision is made to discharge the patient from the emergency room, it is advisable to make a referral to a child and adolescent psychiatrist for ongoing care and treatment. Among those adolescents who make a suicide attempt, there is significant heterogeneity in the clinical presentation, and treatments should be tailored according to the youth’s developmental level. Goals of outpatient treatment are stress reduction and prevention of any future suicide attempts.

Problem Solving

These therapies help adolescents to identify triggers of suicidal thoughts and to develop behavioral alternatives to suicide so that they can cope with such situations if they arise in the future. As learning is often context dependent, exposure tasks are usually included within cognitive therapy approaches. During exposure tasks, the adolescent is asked to reimagine the

situation that led to the suicide attempt and then to imagine an alternative way of confronting such situations differently in the future in order to avoid making another attempt.

Family Therapies

Therapy approaches can also be extended to the whole family. Family therapies are structured and aim to provide education and promote understanding of suicidal behaviors. Issues of validation (“no one understands me”) can also be addressed within the family framework.

Other Therapies

Depending upon the presenting problem (e.g., substance use issues, depression, bullying, etc.), additional approaches may be suggested by the outpatient provider.

CONCLUSION

Suicide in children and adolescents is a complex and emotional problem for families and societies nationally and internationally [9]. Risk factors for suicide have been reviewed including personal characteristics, psychopathology of those committing suicide, history of previous suicide attempts, sexual orientation, familial factors, and access to lethal means of suicide. Protective factors include social support and religion. Principles of prevention have been considered including school-based programs, screening tools, skills training, Gatekeeper training, community-based programs, and health-care programs. Management includes principles involved in management before and after self-harm. Also considered are family therapies and therapies aimed at specific problems such as depression, bullying, substance abuse, and others [10]. Clinicians should be actively involved with their communities to seek prevention of suicide in children and adolescents.

ABSTRACT

Substance use and abuse remains a major public health issue of adolescents throughout the world, including the United States. Encouragement by the media, peers, and many adults along with easy access to drugs of all types continues to lure countless millions of youth into use and abuse of many drugs. Results of the 2013 US Centers for Disease Control and Prevention Youth Risk Behavior Surveillance notes that there is significant abuse of drugs including illicit drugs but also prescription medications including stimulants, synthetic narcotics, and “recreational” cough syrups. This review considers various drugs, including tobacco, alcohol, marijuana, cocaine, heroin, hallucinogens, inhalants, and designer drugs.

Keywords: adolescence, health, substance abuse, public health, behavior

INTRODUCTION

The United States SAMHSA (Substance Abuse and Mental Health Services Administration) directs a survey every year of the US population (non-military, non-institutionalized) who are 12 years of age and older [1]. The publication is called NSDUH (National Survey of Drug Use and Health) and its 2013 report noted that 24.6 million Americans 12 years of age and older used illicit drugs in that they had used an illicit drug during the month prior to the survey [1]. Racial disparities in illicit drug use are being identified by various studies [2, 3].

It is important that clinicians who are caring for adolescents be directly involved in teaching their patients how to prevent the use and abuse of drugs (Table 1); clinicians can also remain active in the management of substance abuse disorders, if it develops in their patient [4-11]. Adolescent exposure to illicit drugs can lead to a lifetime of medical and psychiatric effects [7]. The impact of illicit drugs, when taken during pregnancy, can be devastating to the fetus and the child [12]. Drug addiction involves mesocorticolimbic circuitry dysfunction and can be a lifelong problem, especially from cannabis, cocaine, nicotine, alcohol, and ecstasy [13]. A number of factors are involved in drug addiction, including the role of serotonin, ghrelin, and other factors that are under study [14, 15]. Death from the use of illicit drugs continues, as is seen with the use of heroin, amphetamines, inhalants, and others [16].

Table 1. Drugs of abuse

– Tobacco
– Marijuana
– Alcohol
– Cocaine
– Heroin
– Amphetamine
– Methamphetamine
– MDMA [<i>Ecstasy</i>]
– Flunitrazepam [<i>Rohypnol</i>]
– Gamma-hydroxybutyrate [<i>GHB</i>]
– Ketamine [<i>Ketalar</i>]
– LSD { <i>lysergic acid diethylamide</i> }
– PCP { <i>phencyclidine</i> }
– Tryptamines
– Barbiturates
– Designer drugs
– <i>Sports Doping and Performance Enhancing Drugs</i>

Screening for substance abuse [17] is critical because the neuro-psychiatric changes caused by some drugs (i.e., Ecstasy) may be irreversible and there have been reports of acute psychosis following marijuana and phencyclidine (PCP). One should also consider the likelihood of co-morbid conditions (see Table 2) in any adolescent or young adult with a history of continuing or repeated substance abuse; these conditions include ADHD, especially when associated with or secondary to a learning disorder where treatment is protective. Risk factors for drug abuse are reviewed in Table 3, while Table 4 considers non-specific

indicators of drug abuse and Table 5 outlines protective factors for drug abuse. Screening tests may be helpful, such as the CRAFFT questions for alcohol use. The role of prescription medication dependence must be considered also by clinicians [18].

A major contribution that the primary care clinician can provide is to establish a medical home for all youth including those with substance use [19]. The success of management is partially based on the underlying genetics of addiction for a person, especially with opioid, alcohol, and cocaine dependence [20]. Straightforward talk with teens about drug use is important in the screening process, though the teenager's estimates are often lower than the actual use. The clinician can work with the community in supporting community-based drug abuse prevention programs. Models of treatment are available ranging from brief to intensive management [21]. Attention to improving sleep dysfunction in those with substance dependence and depression is an important goal in overall management of these person [22].

Table 2. Co-morbid disorders of substance abuse disorder

Adolescents generally progress from initial drug use to more serious drug use behavior in a pattern that is recognizable (see Table 6). At first, there is curiosity about drugs, though no drug use may be occurring. A need for acceptance by some peer group along with a low self-esteem may lead to experimentation with some drugs—often the “gateway” drugs— tobacco, alcohol and/or marijuana.

At some point the euphoria some drugs deliver is felt by the adolescent, typically at weekend parties or when combined with other substances. In some youth, there develops a state of actively seeking out the euphoria of drug use with widening of the types of drugs used (i.e., cocaine, Ecstasy, heroin, others), using personal drug paraphernalia, buying and/or stealing drugs on a regular basis, and becoming more dependent on one or more drugs. There is often a drop in grades, change of clothes, switching of peer group, and a strong denial of using/abusing any drugs. Seeking the euphoric state becomes the center piece of the individual's life which becomes out of control as the menu of drugs tried increases in scope. There may also be evidence of depression, worsening mood swings, acting out behaviors, suicide, violence, malaise, and lethargy. At this stage, the abuser seeks the euphoric state to feel “normal.” This progression from experimenting with drugs to abuse and burnout can be seen over months to years.

Table 3. Risk factors for substance abuse in adolescents*

Genetics	Alcoholism among 1st or 2nd degree relatives Male gender
Self/Individual/Personal	Abuse Early onset of drug use Early sexual activity / homosexuality Attention deficit disorders Antisocial behavior Aggressive temperament Depression Poor self-image Learning disorders Parental rejection Lack of self-control Low self-esteem Euphoric/mood altering effects of drugs Body modification (as cutting)
Family	Dysfunctional family dynamics Permissiveness Authoritarianism Parental conflict, divorce, separation Poor supervision, lack of supervision Poor parental role modeling
Community/Environmental/ Societal	Easy availability of drugs and alcohol Acceptance of drug use behavior Poor general quality of life in the neighborhood Media influence Criminal activities in neighborhood Cultural and religious sanction Low religiosity Employment Increased use of drugs and alcohol in certain ethnic groups
Peer Group Influence	Substance using peers Rebellion Rites of passage of puberty Risk-taking behavior Curiosity Desire to belong Independence Early tobacco use
School/Academic	Poor school performance Poor school environment Truancy

*Modified with permission: Patel DR and Greydanus DE: Substance abuse: a pediatric concern. *Indian J. Pediatrics* 66:557-567, 1999.

Table 4. Non-specific indicators of substance abuse*

Physical indicators	Academic indicators	Behavioral and psychological indicators
Unexplained weight loss Hypertension Red eyes Nasal irritation	Deterioration of short-term memory Poor judgment Falling grades	Risk taking behavior Mood swings Depression, withdrawal Panic reaction
Frequent “colds” or “allergies” Hoarseness Chronic cough Hemoptysis Chest pain Wheezing Frequent unexplained injuries Needle tracks Blank stares into space Scratch marks Tattoos Excessive acne Testicular atrophy Malaise	Frequent absences Truancy Conflicts with teachers Suspensions Expulsion	Acute psychosis Paranoia Lying Stealing Promiscuity Conflict with authorities and family members Runaway behavior Altered sleep pattern Altered appetite Poor hygiene Loss of interest in extracurricular activities Drug using peers Preferences for dress, music, movies, identifying with drug using culture Drug paraphernalia

*Used with permission: Patel DR and Greydanus DE: Substance abuse: a pediatric concern. *Indian J Pediatrics* 66:557-567, 1999.

Table 5. Factors protective of substance abuse in adolescents*

– Nurturing home environment – Good communication within family – Supportive parents, intact family, appropriate adult supervision – Positive self-esteem – Assertiveness – Social competence – Academic success – Good schools – Good general health – High intelligence – Positive adult role models – Peer group with positive personal attributes – Religious involvement – A personal sense of morality

*Used with permission: Patel DR and Greydanus DE: Substance abuse: a pediatric concern. *Indian J Pediatrics* 66: 557-567, 1999.

Table 6. MacDonald's stages of substance abuse*

Stage	1. Learning the mood swing	2. Seeking the mood swing	3. Preoccupation with the mood swing	4. Using drugs to feel normal
Mood Alteration	Euphoria Normal	Euphoria Normal Some pain	Euphoria Normal Definite pain	Euphoria Normal Marked pain
Feelings	Feels good; few consequences	Excitement; early guilt	Euphoric highs; doubts, including severe shame and guilt; depression, suicidal thoughts	Chronic guilt; shame, remorse, depression
Drugs	Tobacco Marijuana Alcohol	All of the above plus inhalants, hashish, depressants, methamphetamine, prescription drugs	All listed plus psilocybin, PCP, LSD, cocaine	Whatever is available
Sources	Peers	Buying	Selling	Any way possible
Behavior	Little detectable change; moderate after-the-fact lying	Dropping extracurricular activities and hobbies; mixed friends (straight and drug users); dress changing; erratic school performance and truancy; unpredictable mood and attitude swings; manipulative behavior	"Cool" appearance; straight friends dropped; family fights (verbal or physical); stealing (police incidents); pathological lying; school failure; truancy, expulsion, jobs lost	Physical deterioration (weight loss, chronic cough); severe mental deterioration (memory loss and flashbacks); paranoia, volcanic anger; school dropout; frequent overdosing
Frequency	Progress to weekend use	Weekend use progressing to four to five times per week; some solo use	Daily; frequent solo use	All day every day

PCP = phencyclidine; LSD = lysergic acid diethylamide.

DSM-5

The American Psychiatric Association published its 5th edition of the "Diagnostic and statistical manual of mental disorders" (DSM-5) in 2013 [23]. Some changes were seen in this 5th edition in contrast to the 4th edition [24] (see the preface). The DSM-5 provided changes in the diagnostic criteria of substance related disorders (SRD). In the previous edition (DSM-IV-TR, 2000), SRDs were classified as substance use disorders (SUD) and substance induced disorders (SID). SUD was also identified as "abuse" and "dependence" disorders according to specific substances (i.e., opioid abuse and dependence, alcohol abuse and dependence, and so forth). SID included such classifications as intoxication, withdrawal, delirium, anxiety and others as induced by specific substances (i.e., opioids, alcohol, others) [25]. The diagnoses of "abuse" and "dependence" categories needed their own specific criteria. Abuse could be

diagnosed by meeting only one of those criteria while dependence needed at least three of those criteria.

In the DSM-5 SUD and SID terms remain but in SUD the previous diagnostic distinction between abuse and dependence was removed and a single category was developed called “substance use disorder” that ranged from mild to severe. A mild disorder is defined as meeting 2-3 of the SUD criteria versus 4-5 for moderate and 6 or more for a severe disorder (American Psychiatric Association, DSM-5, 2013).

In the DSM-5 there was an increase in the diagnostic threshold in that at least 2 criteria (versus 1) are required for an SUD. “Craving” is added as a new criterion and refers to an intense desire or urge for a drug. Also, the criteria, “problems with law enforcement” was removed since laws vary from country to country and over time.

A variety of illicit drugs are reviewed in this chapter with prevalence mainly based on the US Centers for Disease and Prevention (CDC) 2013 Youth Risk Behavioral Surveillance (YRBS) [2]. The reader is encouraged to review this document. A number of other drug issues are considered in this report including taking steroids without a doctor’s prescription, taking prescription drugs without a doctor’s prescription, and ever injecting any illegal drugs. This survey reveals that 3.2% of US high school students had taken steroid pills or shots without a doctor’s prescription; this increased from 2.7% in 1991 to 3.2% in 2013 [2].

The report also notes that 17.8% of students had taken prescription drugs without a doctor’s prescription one or more times during their life; these drugs included Oxycontin, Percocet, Vicodin, codeine, Adderall, Ritalin, or Xanax. The prevalence was 20.7% in 2011. Also, 1.7% of students had used a needle to inject any illegal drug into their body one or more times during their life; this prevalence was 2.3% in 2011 [2]. The survey also noted that 22.1% of students had been offered, sold, or given an illegal drug by someone on school property during the 12 months prior to the survey; this prevalence was 24.0% in 1993.

ENERGY DRINKS

The negative effects of energy drinks often containing large amounts of caffeine is becoming an increasing problem in adolescents and young adults; cardiovascular and neurological adverse effects are particularly seen [26]. The DSM-5 lists four caffeine-related disorders: caffeine intoxication, caffeine withdrawal, other caffeine-induced disorders, and unspecified caffeine-related disorders [23].

DESIGNER DRUGS

Clandestine chemists and surreptitious laboratories are developing a wide variety of designer drugs or “legal highs” which are analogs of such drugs as opioids, cannabinoids, phencyclidine, amphetamine, and others [27-32]. Their development can be traced to the 1960s but their production has escalated since 2008. They are used to mimic the effects of these drugs such as synthetic cannabinoids which mimic the psychoactive effects of cannabis and have been called spice drugs or K2 drugs. Cathinone is a natural occurring amphetamine analogue that is found in the *Catha edulis* plant leaves and synthetic cathinones (such as

mephedrone or 3,4-methylenedioxypyro-valerone[MDPV]) are derivatives of phenylalkylamines which as amphetamine-like effects. Some are piperazine derivatives. Designer psychostimulants have been developed to mimic the effects of amphetamines, cocaine, or ecstasy. Methoxydine and methoxetamine are designer drugs with phencyclidine effects.

They may be sold on the internet or elsewhere as “bath salts” or “plant foods” and marked as “not for human consumption” in order to escape legal prosecution. Many adverse side effects may result depending on the exact product, its doses, what impurities it contains and other factors. Their use can lead to negative effects that are cardiovascular, neurological, renal, psychotic and others including death. Management of adverse reactions can be difficult and complicated by lack of knowledge of the patient and clinician what was taken. Negative reactions to synthetic cathinones (“bath salts”) for example, focus on lowering the agitation and psychosis that are seen along with supporting renal perfusion; benzodiazepines and antipsychotics are used [33]. Persons seeking euphoric experiences, including adolescents and young adults, should be educated about these designer drugs that are increasingly becoming available outside local laws.

TOBACCO

Tobacco remains a widely used and abused drug that enjoys a high level of acceptance by society, including governments that allow it to be grown for profit. In a 1999 national survey conducted by the Centers for Disease Control, one in every eight middle-school students reported using some form of tobacco (cigarettes, cigars, bidis, or kreteks) in the past month. Bidis (or beedies) are brown, hand-rolled, flavored tobacco while Kreteks (clove cigarettes) contain a mixture of tobacco and cloves; both are imported from Indonesia. Electronic cigarettes (E-cigarette) are now available on the market place which also can pose a threat to adolescents, though more research is needed [34, 35]. The role of nicotine as a gateway drug has been shown by research [36, 37]. The DSM-5 lists a number of tobacco-related disorders: tobacco use disorder (mild, moderate, severe), tobacco withdrawal, other tobacco-induced disorders, and unspecified tobacco related disorders [23].

The 2013 Youth Risk Behavioral Surveillance (YRBS) reports that 41.1% of high school students had ever tried cigarette smoking with a prevalence of 42.5% in males and 39.6% in females [2]. The prevalence was higher among white and Hispanic students than black students. The prevalence of ever smoked cigarettes from 70.1% in 1991 to 41.1% in 2013. This survey also revealed that 9.3% had smoked a whole cigarette for the first time before age 13 years and this dropped from 23.8% in 1991 to 9.3% in 2013. Also, 15.7% of students had smoked cigarettes on at least one day during the 30 days prior to the survey and this had dropped from 27.5% in 1991 to 15.7% in 2013. It also noted that 5.6% of students had smoked cigarettes 20 or more days during the 30 days before the survey and this dropped from 12.7% in 1991 to 5.6% in 2013. Among the 15.7% who currently smoke cigarettes, 8.6% had smoked more than 10 cigarettes per day on the days they smoked during the 30 days before the survey; this dropped from 18.0% in 1991 to 8.6% in 2013 (Kann, 2013).

Among the 15.7% who currently smoked cigarettes, 48.0% had tried to quit smoking cigarettes during the 12 months before the survey; this prevalence dropped from 57.4% in 2001 to 48.0% in 2013. Also, 8.8% of students had ever smoked at least one cigarette daily

for 30 days and this dropped from 20.0% in 2001 to 8.8% in 2013. The 2013 survey reported that 4.0% of students had smoked cigarettes on all 30 days during the 30 days before the survey; this prevalence dropped from 9.8% in 1991 to 4.0% in 2013. Also, 3.8% had smoked cigarettes on school property on at least one day during the 30 days before the survey; this prevalence dropped from 13.2% in 1993 to 3.8% in 2013.

The 2013 report reveals that 8.8% of students had used smokeless tobacco on at least 1 day during the 30 days before the survey; this dropped from 11.4% in 1995 to 8.8% in 2013. It also notes that 12.6% of students had smoked cigars, cigarillos, or little cigars on at least one day during the 30 days before the survey; this decreased from 22.0% in 1997 to 12.6% in 2013. It also noted that 22.4% of students had reported current cigarette use, current smokeless tobacco use, or current cigar use; this prevalence had decreased from 43.4% in 1997 to 22.4% in 2013 [2].

General

The smoke of cigars is more alkaline than that of cigarettes, dissolves more easily in saliva, and achieves the desired dose of nicotine without the need to inhale smoke into the lungs. Cigars are capable of providing high levels of nicotine at a rate fast enough to produce clear dependence, even if the smoke is not inhaled. The risk of lung cancer for cigar aficionados (well-known to cigarette smokers), is much higher than once thought. This rate increases more for cigar smokers if they were previous cigarette smokers. A class of carcinogenic compounds known as tobacco-specific, N-nitrosamines (TSNA) is present in cigar smoke at significantly higher levels than in cigarette smoke. Examination on a “per gram of tobacco smoke” basis reveals that tar, carbon monoxide, and ammonia are produced at greater quantities by cigars. When equal doses are applied, the tar produced by cigars exerts a greater tumor-producing activity in mice because of higher concentrations of carcinogenic polycyclic aromatic hydrocarbons.

Nicotine, an important component in tobacco, is highly addictive and a number of genes are involved such as the nicotinic receptor gene cluster on chromosome 15q25 [38]. Current research shows that adolescents experience symptoms of nicotine dependence long before they become everyday smokers. Early and continued intervention, including the clinical use of such instruments as the HONC (hooked on nicotine checklist), is required because initiation of smoking during adolescence is related to drunkenness-oriented alcohol use and an increased risk for future substance abuse. The most powerful predictor of drunk driving in this research is regular smoking at age 14.

Nicotine is absorbed over various sites: lungs, buccal mucosa, skin, and gastrointestinal tract. Approximately 10 mg of nicotine is found in one cigarette; when smoked, 1.0 to 3.0 mg of nicotine is absorbed by the user. Nicotine is rapidly taken up by the brain’s nicotinic acetylcholine receptors that are found in numerous non-cholinergic presynaptic and postsynaptic areas. The tobacco addict has chronic exposure to many dangerous chemicals, including nicotine, tar, carbon monoxide, arsenous oxide, radioactive polonium, benzopyrene, others. The addicted cigarette abuser becomes an adult with significant risks for the many well-known complications of this drug—lung cancer, emphysema, laryngeal carcinoma, other

cancers, heart disease, and many other disorders. Lung cancer in female adult smokers is now more common than breast cancer.

A common condition noted in smokers and reverse smokers is keratosis of the mucosal palate posterior to the rugae. This was originally described in 1926 and is caused by the concentrated hot steam of smoke and chemicals producing a nicotine or “smoker’s patch.” Reverse smoking has been associated with dysplastic and malignant changes over time. Recent research also notes negative effects which occur from smoking during pregnancy, including lower birth weight and attention deficit hyperactivity disorder. Nicotine staining of the teeth, crow’s feet from the occlusion of micro-arterioles near the eyes, bad breath, cough, and dyspnea are also well-recognized and widespread stigmata of smoking. Passive smoking is also known to be dangerous to those exposed to the smoking of others. Oral cancer is a serious consequence of using chewing tobacco.

It is important for clinicians caring for adolescents to join the struggle to limit the use of tobacco by adolescents. For example, advertising to youth must be prevented, and efforts to reduce the acceptance of tobacco by society strengthened. The prevention and reduction of adolescent tobacco use and abuse must be encouraged on a national and statewide level. On a local level, a broad range program is recommended that targets the family, community, and schools.

Pharmacologic Management

Table 7 reviews current pharmacologic management options for tobacco addicts who are motivated to quit using tobacco products [39]. Clinicians should take every opportunity to remind tobacco-addicted teens that their habit is very dangerous and help is available when they are ready to stop. Psychosocial issues in the lives of teen smokers and underlying cues to smoking should be reviewed with the adolescent. Special situations may arise, such as the pregnant adolescent who also smokes. A variety of nicotine replacement (NT) products are produced, as reviewed in Tables 7 and 8; the rate of quitting smoking is doubled by use of these products for the motivated smoker (i.e., 30%), in contrast to those seeking to stop smoking without pharmacologic agents (i.e., 15%). The choice of NT product is patient-driven; teens should not smoke while on NT products, though no overt negative sequelae have been reported in such cases.

The NT patch is prescribed for two months (changed each morning), using a high strength patch for one month, and then the lower dose for one more month (see Table 8). The patch is not placed over a site with hair. Up to half will develop local dermatitis, usually improved with local hydrocortisone application. The patch is applied only while awake if patch-induced secondary vivid dreams or insomnia develop. The NT gum (nicotine polacrilex) has a bitter taste that many teens do not like; some youth feel embarrassed while choosing the nicotine gum. If the tobacco addict smokes over 25 cigarettes a day, prescribe the 4 mg gum; eventually lower the patient to the 2 mg gum. Since acidic liquids reduce nicotine absorption, they should not be used for 15 minutes before gum use and while chewing. Instructions to give patients who chew this gum are provided in Table 9. Adverse effects of this gum, though temporary, include dyspepsia, mouth soreness, jaw ache and hiccups.

Table 7. Pharmacologic products available in the USA to treat tobacco addiction*

Nicotine Medications	
Nicotine gum	– Nicorette OTC – Nicorette DS OTC
Nicotine patch	– Nicoderm CQ(SmithKline Beecham) OTC – Nicotrol Patch (McNeil) OTC
Nicotine inhaler	– Habitrol (Novartis)
Nasal spray	– Prostep (Lederle) – Nicotrol Inhaler (McNeil) – Nicotrol Nasal Spray (McNeil)
Non-Nicotine Medications Bupropion	- Zyban SR (Glaxo Wellcome) - Sustained-release tablets

Table 8. Nicotine patch regimens*

Brand	Duration	Dosage
Nicoderm CQ and Habitrol	4 weeks then 2 weeks then 2 weeks	21 mg/24 hours 14 mg/24 hours 7 mg/24 hours
Prostep	4 weeks then 4 weeks	22 mg/24 hours 11 mg/24 hours
Nicotrol	8 weeks	15 mg/24 hours

*Reprinted with Permission from: Patel DR and Greydanus DE: Office interventions for adolescent smokers. State of the Art Reviews: *Adolescent Medicine* 11 (3): 1-11, 2000.

Table 9. Recommendations for use of nicotine gum

Chew a piece each hour for 6 weeks. Then, chew a piece every 2 hours for 3 weeks. Finally, chew a piece every 4 hours for 3 weeks. Maximum limit is 30 pieces per day for the 2 mg gum and 20 pieces per day for the 4 mg gum. Chewing instructions: – Chew slowly until a peppery taste appears (often after 15 chews) – Then put the gum between the cheek and buccal mucosa until the peppery taste has disappeared (often one minute) – Start chewing again and repeat the above cycle – Get rid of the gum when the peppery taste is gone (often 30 minutes).
--

The nicotine inhaler is designed to mimic the hand-to-mouth movement of the smoker; 4 mg of nicotine are delivered from the cartridge which contains about 10 mg overall (see Table 7). Low nicotine levels are produced and the user inhales 6-16 cartridges daily. Adequate nicotine absorption is accomplished with 80 inhalations over 20 minutes; absorption is through the oral mucosa. It is prescribed for 3 months and then slowly tapered off over 3 months. Adverse effects that often improve over time include coughing, dyspepsia, irritation of the mouth and throat, and nasal irritation.

The nicotine nasal spray is provided as one to two doses (1 to 2 mg of nicotine) per hour over 3 months; there is a rapid rise in nicotine serum levels (see Table 7). It is prescribed as a minimum of 8 doses per day, not over 40 per day or over 5 inhalations per hour. Bronchospasm may occur and the nasal spray is not used for nicotine addicts with asthma. Other adverse effects include cough, rhinitis, nasal irritation, sneezing, and water eyes. The use of electronic cigarette for the cessation or reduction of smoking in adults remains under active research [40].

Non-Nicotine Therapy

The use of bupropion (see Table 7) in the nicotine addict who is motivated to quit smoking is helpful in up to 40% of cases; its relative success is attributed to the drug's ability to lower the classic nicotine craving while improving the nicotine-withdrawal problems of weight gain and depression. It was found to be twice as effective as placebo. It is prescribed as Zyban in a sustained-release form that is provided as 150 mg a day for three days; if tolerated, it is increased to 150 mg twice daily. The dose should not exceed 300 mg a day. Additionally, the second dose should not be given less than 8 hours after the first to reduce the incidence of a seizure. Though NT replacement therapies should not officially be started while the adolescent is still smoking, it is acceptable to start the teen smoker on bupropion while still using nicotine; a date of stopping the tobacco should still be negotiated while providing the bupropion. Bupropion is contraindicated in adolescents who have overt seizures and those with factors that increase the risk for seizures; the latter includes those with a history of epilepsy, an eating disorder, central nervous system tumor, and any medications that may lower the seizure threshold. Bupropion is contraindicated in those on MAO inhibitors. Bupropion adverse effects include insomnia, skin reactions, tremors, headaches, and dry mouth.

Clonidine and nortriptyline may be useful to some late adolescents and adult smokers to help them quit using tobacco. Various medications have been studied but not shown to help improve the craving for nicotine; these include buspirone, mecamlamine, naltrexone, doxepin, and oral dextrose. Another smoking cessation product is varenicline tartrate (Chantix®), an alpha-4 beta-2- nicotinic acetylcholine receptor partial agonist that binds to central nervous system receptors with a greater affinity than nicotine. It is FDA approved for adults with nicotine addiction and may be more effective than bupropion. Abstinence rates are 22% versus 16% for bupropion and 8% for placebo. In the short term, 44% of study patients quit smoking v. 30% using Zyban. Starting dose is 0.5 mg per day for three days, twice a day for 4-7 days, then 1 mg twice daily. Chantix® decreases the pleasure of nicotine use and lessens the withdrawal craving. The major side effect is nausea, but weight gain is not a problem. There are reports of suicidality, agitation, hostility, and agitation [7]. The use of cytisine, a partial agonist that binds the nicotinic acetylcholine receptor, is under study [41]. The use of a nicotine vaccine is also under active research [42, 43].

MARIJUANA

Marijuana (cannabis) remains a popular euphoric and hallucinogenic drug for millions of youth and adults; it has many names, including “pot,” “hash,” “weed,” “doobs,” “BC Bud,” “Ganja,” “grass,” “smoke,” and others. It is the most widely used illicit drug in the United States, accounting for up to 85% of the illicit drug trade. The 2013 YRBS reported that 40.7% of high school students had used pot one or more times during their life [2]. Previous CDC surveys noted that the category of “ever used marijuana” had increased from 1991-1997 (31.3% to 47.1%); it did then decrease from 1997 to 2013 (47.1% to 40.7%) [2]. The survey noted that 8.6% of students had tried pot for the first time before age 13 years and 23.4% of students had used pot one or more times during the 30 days prior to the survey. The prevalence of having ever used pot was higher among males versus females and higher among black and Hispanic youth versus white youth. In the 2013 National Survey on Drug Use and Health marijuana was the most commonly illicit consumed drug with 19.8 million users 12 years of age and older over the past month of the survey [1]. From 2006 to 2013 the number of persons using daily cannabis almost doubled in this survey.

This controversial drug is derived from *Cannabis sativa* or *C indica* (hemp plant) and the active euphoric chemical is delta-9-tetrahydrocannabinol or THC. It is present in the dried leaves, stems, seeds, flowers (sensimilla) and oil. This major lipophilic drug works on the cannabinoid receptors (ECS) in the mesocortical and limbic systems. The marijuana of the 1960s and 1970s’ hippie generation contained only 2% THC, while the Hawaiian sensimilla product was about 3% THC. Today’s street pot can vary from 3 to 7%+ THC content, while cultivated sensimilla can contain 7 to 13%+. A popular brand of pot is BC Bud, a product imported by the ton from Canada at \$3000- 8,000 dollars per pound; it is grown in British Columbia and may contain up to 24% active ingredients. Many growers, commercial exporter consortiums (Canada), a significant fraction of the public and their elected officials, as well as active pot users are actively advocating for the legalization of marijuana.

Cannabis contains over 60 phytocannabinoids including cannabitol (or CBN--metabolite of THC), cannabidiol (or CBD--isomer of THC), cannabigerol (or CBG-- alpha-2-adrenergic receptor agonist), tetra-hydrocannabivarin (or THCV;THV--TCH homolog), and cannabichromene (or CBC) [8, 11]. Many other chemicals are found in this complex plant, including terpenoids, and endocannabinoids (such as 2-AG [2-arachidonoyl glycerol] and anandamide [arachidonoyl ethanolamide]). The role of pot smoking as a gateway drug is well-known and many smokers also use tobacco, alcohol, and other drugs.

Commercial preparations of synthetic cannabinoids include nabilone (schedule II drug), dronabinol (synthetic THC in sesame oil; schedule III drug), and nabiximols (phytocannabinoid marketed in Canada). Dronabinol capsules were approved on May 31, 1985 by the US Food and Drug Administration (FDA) for nausea and emesis management due to cancer chemotherapy; the US FDA also approved dronabinol on December 22, 1992 for persons with AIDS who have anorexia associated with weight loss. Oral nabilone was approved by the US FDA on December 26, 1985 for nausea and vomiting due to cancer chemotherapy. Though these and other cannabis products are suggested for various other medical disorders, they are not approved by the FDA. Smoking marijuana is not approved by the FDA nor leading medical organizations because there is no research to support smoking pot and because of the many potential adverse side effects from cannabis smoking

(Greydanus, 2014, 2015). In Canada the oromucosal spray, nabiximols, is indicated for management of cancer pain in addition to neuropathic pain and spasticity seen in persons with multiple sclerosis.

Though usually smoked, marijuana can also be eaten in such homemade concoctions as cookies, brownies, and spaghetti. The typical cannabis cigarette (joint) usually contains approximately 20 mg of THC obtained from about a gram of leaves and buds; however, much variation can be noted. The “blunt” is another popular way to smoke pot and consists of a cigarette with marijuana added to a hollowed cigarette. “Pot” is often combined with other drugs, such as phencyclidine, though glutethimide and methaqualone were also popular in the past as additives. PCP (phencyclidine) is frequently dissolved in an organic solvent, such as formaldehyde, in which a joint or hand-rolled cigarette is first dipped, dried, and then smoked. This preparation is variously referred to as “wet” “water,” or “Sherms”; the latter term refers to the well-known tobaccoist Nat Sherman. This is a good reason for doing a urine drug test with informed consent and assent of a using teenager.

Marijuana use results in a potent sensation of euphoria (“buzz”) that is noted within minutes of its use, and which can last for hours. Both THC and its metabolites are highly lipid soluble and are stored in fatty tissue. Serum half-life is 19 hours. Marijuana can be found on urine drug screen and stool for as long as one month following regular use, and ten days after a single use. The behavioral effects are mediated by cannabinoid receptors and results in the release of dopamine in the nucleus accumbens. The effects of THC also include relaxation, time and perceptual distortions, and heightened sensory experiences such as listening to music, watching television, or eating (“getting the munchies”). Some drugs (alcohol or diazepam) may potentiate the sedative effects of marijuana, while other drugs (cocaine or amphetamines) worsen the stimulatory effects of marijuana.

A large number of potential adverse effects are seen with smoking cannabis, including cardio-vascular, pulmonary, gastrointestinal (cannabis hyperemesis syndrome), dental, and central nervous system effects [8, 11]. Cardiovascular adverse effects can include arteritis, cardiomyopathy, myocardial infarction, sudden cardiac death, transient ischemic accident (TIA), cardiovascular accident (CVA), and cardiac arrhythmias. Pulmonary side effects can include chronic cough, allergic hypersensitivity, bronchitis, bullous emphysema (COPD: chronic obstructive pulmonary disease), pneumothorax/pneumomediastinum, pulmonary dysplasia, pulmonary tuberculosis, other respiratory infections, and even dust disease (talcosis) in hemp workers.

Potential adverse dental effects can include dental caries, dental dysplasia, gingival enlargement, gingivitis, leukoedema, nicotinic stomatitis, oral infections, periodontal disease, poor dental health, uvulitis, and xerostomia. Potential adverse effects on the offspring of females smoking cannabis while pregnant include low birth weight, preterm labor, small for gestational age, treatment in a neonatal intensive care unit, and various childhood effects such as inattention problems, problem-solving problems, aggression, executive function dysfunction, problems with memory and processing information, and depressive symptoms.

Cannabis poisoning can arise from consuming oral cannabis products and this is increasing being seen in young children whose parents are pot smokers. Cannabis smoking (including Spice drugs) increases risks for MVAs (double or more) and this can be worsened when combined with other drugs (i.e., alcohol, others). If one has smoked cannabis, 8 or more hours should pass before driving a motor vehicle. Pot smoking also increase road rage.

The central nervous system of young adolescents is very sensitive to cannabis and adverse effects may include decline in IQ, decreased coordination, distorted visuospatial perception, impaired executive function, impaired novel learning, impulsivity, inattention, memory loss, neuropsychiatric disorders (i.e., psychosis), and cannabis dependence. The DSM-5 has listed a number of cannabis-related disorders including cannabis use disorder (mild, moderate severe), cannabis intoxication (with or without perceptual disturbances), cannabis withdrawal, other cannabis-induced disorders, and unspecified cannabis-related disorders [23].

Management of cannabis use disorder is very difficult and there is no pharmaceutical agent approved for its management. Research continues to find medications that may be of help to those with cannabis use disorders and these include alpha 2 adrenergic agonists, antipsychotics (atypical), benzodiazepines, cannabidiol, dronabinol, gabapentin, lithium, lofexidine, nabilone, nabiximols, N-acetylcysteine (NAC), N-arachidonylethanolamine (anandamide), nefazodone, 2-arachidonoyl glycerol (2-AG), and others [11].

Therapy is typically prescribed and its efficacy may be low because of lack of motivation for the person with cannabis dependence to stop their drug of choice. Approximately 25% of the 19.8 million cannabis users in the United States meet the DSM-5 criteria for cannabis use disorders. Many fail to seek treatment and this tends to be due to failure to recognize the severity of their disorder and this denial may reflect their own brain dysfunction. Of the 7.6 million persons aged 12 or older who need treatment for an illicit drug use problem in 2013, only 1.5 million (19.5%) received management in a specialty program [11]. Of the 6.1 million persons who needed but did not receive management, only 395,000 (6.4%) reported they were aware of a need for treatment.

ALCOHOL

Alcohol continues to be among the most used and abused “licit” substances (#1 choice of 29% youth) that enjoys a wide range of societal acceptance [44]. Alcohol is the leading cause of substance use morbidity and mortality contributing to 8,000 deaths each year. Surveys have revealed that US high school seniors have a lifetime prevalence of over 80%, with over 50% noting alcohol use during the previous survey month, and 4% admitting to daily use. The average age that alcohol is first misused is age 12. The prevalence of alcohol use is higher among white and Hispanic youth than among black youth. It is important to ask youth if they drink and if so, what their drinking pattern is; repeated use of alcohol or other substances is not part of normal adolescent defiant behavior. The CRAFFT screening test for adolescent substance abuse is an easy to use instrument for screening drug use [17, 45].

About half of adolescents who are victims of a motor vehicle accident or suicide were drinking before their death. The most common pattern of alcoholic consumption is binge drinking, as defined by 5 drinks in a row in males, and four in females. Blacking out spells are frequently a result of binge drinking behavior. Binge drinking is directly related to drunk driving, increased sexual activity (and teen pregnancy), smoking, dating violence, attempted suicide, and other substance abuse.

The 2013 Youth Risk Behavioral Surveillance (YRBS) revealed that 66.2% of high school students had had at least one drink of alcohol on at least one day during their life [2].

This 2013 survey also revealed that 18.6% of students who had drunk alcohol (apart from a few sips) for the first time before age 13 years of age, 34.9% of students had at least one drink of alcohol on at least 1 day during the 30 days before the survey, and among the 34.9% of students who currently drank alcohol - 41.8% had usually obtained the alcohol they drank from someone who gave it to them during the 30 days before the survey. The prevalence of having ever drunk alcohol was higher in females versus males and higher in Hispanic youth than white or black youth.

The survey noted that 20.8% of students had had five or more drinks of alcohol in a row on at least 1 day during the 30 days prior to the survey. Also, 6.1% of students noted the largest number of drinks they had in a row during the 30 days before the survey was 10 or more. In the 2013 YRBS 21.9% of high school students rode in a car at least once with someone who had been consuming alcohol [2]. Of the 64.3% of high school students who drove a car or other vehicle during the 30 days before the survey, 10.0% had driven after drinking alcohol during the 30 days prior to the survey.

Alcohol Effects

Alcohol is a central nervous system depressant that also induces euphoria in the user; tolerance and psychological dependence may develop, in addition to physiologic dependence in alcoholics. Alcohol drinks vary in their amount of this drug, ranging from 3% to 6% in beer, 12% in wine, and 50% in various liquors. Legal intoxication is usually 0.08 to 0.10 g/dl, though judgment may be impaired at a blood alcohol concentration (BAC) of 0.01 g/dl or lower. Central effects occur at 20-30 ng/dl. Acute intoxication may lead to respiratory depression, coma, and death. Adolescents should be carefully educated about the dangers of alcohol consumption, including the deadly mixture of driving and drinking that kills “innocent” as well as alcohol-consuming victims.

Alcohol dependence is a serious psychiatric disorder in adults, and youth may be involved in this disorder as well. The genetics of alcohol dependence has been studied for decades and its molecular biologic basis is being revealed [46, 47]. The abuse of alcohol depletes a number of so-called “comfort” hormones (opioid peptides, serotonin, gamma aminobutyric acid, dopamine) in addition to inducing stress hormone release (i.e., corticotropin releasing factor). Many adolescents do not stop at the social drinking or experimental stage and rapid progression can develop through the later stages of drug abuse. Youth who abuse alcohol tend to come from families where problem drinking occurs as well as families where problem drinking is absent. The DSM-5 lists a number of alcohol-related disorders: alcohol use disorder (mild, moderate, severe), alcohol intoxication, alcohol withdrawal, other alcohol-induced disorders, and unspecified alcohol related disorders [23].

Medical complications of problem drinking include intoxication, pancreatitis, gastritis, worsening of co-morbid medical disorders (i.e., diabetes mellitus, epilepsy), and toxic psychosis. The alcohol withdrawal syndrome presents with such symptoms as tremors, seizures, hallucinations, and even overt delirium tremens. Youth who abuse alcohol may develop anemia, macrocytosis, and elevation in alkaline phosphatase, bilirubin, uric acid, glutamic-oxaloacetic, gamma glutamyl transpeptidase, or pyruvic transaminases. The diagnosis of alcohol abuse disorder is made mainly by a history of excessive alcohol use, and

not on the basis of a positive serum or drug screening test. The fetal alcohol syndrome and the effect of alcohol on neuronal migration and pruning (apoptosis) in the unborn fetus exposed to intrauterine alcohol are well recognized consequences of alcohol consumption during pregnancy. The mortality risk to the fetus is 5%, while the accidental risk of harm to family members of alcohol users is increased considerably.

Management of Alcohol Abuse

Acute alcohol ingestion is treated with gastric emptying, intravenous fluids, glucose, respiratory support, and sometimes, dialysis. The possibility of additional drug use is suggested by respiratory depression greater than that suggested by the available BAC; head injury may also have occurred in this situation. Medications used in the management of alcohol withdrawal syndrome include clorazepate, lorazepam, chlordiazepoxide, diazepam, and various antipsychotics. Medications approved for the management of adults with alcohol dependence include acamprosate, calcium carbimide, naltrexone, tiapride, and disulfiram. Various medications have been used, but have not been approved for use in adults with alcohol dependence; these include buspirone, carbamazepine, nalmefene, selective serotonin reuptake inhibitors, and tricyclic antidepressants [7]. Mothers Against Drunk Drivers (MADD) and self-help groups (Alcohol Anonymous [AA] and Alateen) are important programs found in many communities that help with the wide-spread problem of alcohol use and abuse in adolescents and adults. Attention to the sleep disruption seen in those abusing alcohol (and other drugs) is important in an overall management strategy [48].

AMPHETAMINES

Amphetamines (Dexedrine, Benzedrine, Desoxyn, chalk, meth, speed, Mollies, black beauties) are classic central nervous system stimulants which lead to a variety of complications, as listed in Table 10.

The DSM-5 lists a number of stimulant-related disorders with regard to amphetamine-type substance: stimulant use disorder- amphetamine-type substance (mild, moderate, severe), stimulant intoxication- amphetamine-type substance, stimulant withdrawal— amphetamine-type substance, other stimulant-induced disorders- amphetamine-type substance, and unspecified stimulant related disorder- amphetamine-type substance [23].

Amphetamines can be taken to develop euphoria, lessen fatigue, improve attention, lose weight, and/or allow continued sports performance. In 2003, high school seniors reported a lifetime use of 14.4%, 9.9% over the past year, and 5.0% over the past 30 days of the survey. In the 2008 MTF, Johnson reported a decline in stimulant use with a prevalence of 4.5% in 8th graders and 6.8% in 12th graders [49]. The use of amphetamines has significantly decreased but is next in frequency of abuse to marijuana. Amphetamine can be abused in various forms—oral, subcutaneous, or intravenous. Amphetamine “look alikes” have become more available through mail order sites or from garage production using simple compounds such as phenylpropanolamine, pseudoephedrine, and ephedrine—including the herbal ma huang.

Table 11. Management of amphetamine overdose

Activated charcoal/magnesium citrate for oral intoxication
Cooling blanket for hyperthermia
Medical control of hypertension and arrhythmias
Haloperidol or droperidol for agitation or delusions
Lorazepam (Ativan®) or diazepam (Valium®) for seizures
Urine acidification with ascorbic acid

While the mechanism of action is not entirely known, amphetamines may act by inhibiting catecholamine re-uptake or facilitating the release of norepinephrine in the presynaptic cleft. Alternatively, they may act as monooxidase inhibitors. They are absorbed through the gastrointestinal tract within 30 minutes and within 5 minutes when used subcutaneously. An initial rush is followed by a prolonged euphoria, alertness, confidence, and excitation. Flushing, sweating, temperature elevation, tachycardia, significant rise in blood pressure, and mydriasis occur. Tolerance is rapid and confusion, irritability, headache, insomnia, seizures, and weight loss may follow. Cerebral hemorrhage and cardiac arrhythmias have been reported. A drug induced psychosis is well known in long time users, but has occurred following a single use. Acute overdose can be life threatening and diagnosis and prompt treatment is necessary (see Table 11).

An infected needle may lead to HIV/AIDS, endocarditis, hepatitis, and other infections [50]. An abstinence or withdrawal syndrome is described in amphetamine abusers, with the development of severe apathy, depression, and hypersomnia. Amphetamine abusers develop tolerance and an overdose can lead to hyperthermia, hypertension, cardiac arrhythmias, seizures, and death. Table 11 outlines basic medical support for an amphetamine overdose; avoid the use of phenothiazines, since rapid decrease in blood pressure and increased seizures activity may result.

Clinicians using stimulant medications to manage adolescents with attention deficit hyperactivity disorder (ADHD) should appreciate the potential for abuse of short acting Adderall® (mixed amphetamine salts) and Ritalin® (methylphenidate) [51]. Ritalin is also called “the smart drug” and “vitamin R” by abusers, who crush the methylphenidate tablets and snort this chemical to obtain an intense euphoria; large doses can lead to seizure activity,

stroke, and psychosis. Published guidelines should be followed carefully when providing stimulant medications to adolescents. This should include the use of the long-acting preparations, such as Concerta®, which have formulations that reduce the risk for dispersion and the quick “buzz.” Another stimulant addition with diminished abuse potential is lisdexamfetamine (Vyvanse®) a prodrug formulation. The long-acting preparations used for the treatment of ADHD do not produce tachyphylaxis, nor have they lead to addiction.

METHAMPHETAMINE

This illicit drug (meth, ice, crystal, fire, glass, chalk, crank) is an N-methyl homolog of amphetamine and has become the stimulant favored by most adolescents, due to its potent stimulant effect on the central nervous system [52]. It is a highly addictive drug prepared by illicit drug laboratories using relatively inexpensive chemicals and sold on the streets and using drug networks. The term “ice” or “crystal” comes from its production as clear, chunky crystals that look like ice; it can also be bought as an odorless, bitter-tasting, white powder that easily dissolves in liquids.

The lifetime use in the 2007 YRBS ranged from 3.7 to 5.3% while the 2013 YRBS noted that 3.2% of students had used this drug one or more times in their lifetime revealing a decreased prevalence of 9.1% in 1999 to 3.2% in 2013 [2]. Methamphetamine is now responsible for one-quarter of illicit stimulant use.

This drug can be taken as a pill or its powder can be snorted, leading to a “high” or euphoria; when inhaled via smoking or taken intravenously, methamphetamine hydrochloride induces an immediate, potent euphoria that is described as a “flash” or “rush” lasting a few minutes. It is this intense feeling that abusers seek leading to rapid addiction with increased dosage and frequency of use. This is not the case with the long acting mixed amphetamine salts preparation (Adderall XR®) that is used to manage patients with ADHD.

Users of this drug note that there is increased wakefulness, less need for sleep, and increased physical activity; sometimes extreme anorexia may develop along with weight loss. The temperature, respirations, pulse, and blood pressure are increased; there may be excited speech. Methamphetamine releases high levels of dopamine and thus can affect body movements and mood in these addicts. Central nervous system cells that contain dopamine and serotonin are damaged, eventually leading to low levels of dopamine, thought dysfunction, and a depressed mood (“blue Tuesdays”). Motor impairment or a Parkinsonian-like movement disorder can develop. Adverse reactions are many and some are listed in Table 12. As with other illicit drugs that are taken intravenously, this drug can lead to various infectious diseases, including sexually transmitted diseases, such as hepatitis B and HIV/AIDS. Urine drug testing remains positive 48 hours and may reflect look alike designer drugs or prescription psycho-stimulants.

The treatment of acute toxicity includes the support of cardiac and respiratory function. Orogastric lavage and activated charcoal may be indicated if oral ingestion of other substances is suspected. Droperidol or haloperidol are more effective than the benzodiazepines in blocking the behavioral effects of amphetamines and produce fairly rapid sedation. However, benzodiazepines are indicated for seizure management and thorazine is contraindicated. Blood pressure is best managed with labetalol or esmolol. Management of

this severe drug addiction is difficult and current research is seeking a medication to block the euphoric effects of methamphetamine to allow the addict to get off the drug, if there is motivation. This antibody-type medication research is part of other addiction research studies seeking to neutralize the euphoric effects of drugs, such as cocaine, heroin, and others. Management of methamphetamine psychosis is difficult but important as is treatment of depression or anxiety related to the use of this drug in order to reduce risks for methamphetamine relapse [53].

Table 12. Adverse effects of methamphetamine

–	Increased aggressiveness with violent behavior
–	Cardiovascular collapse and death

COCAINE

This central nervous system stimulant is an alkaloid made from leaves of the South American plant, *Erythroxylon coca*. There are a number of ways to take this drug: intranasal, intravenous, inhalation, smoking, chewed (coca leaves), or swallowed. Previously, this drug was produced as a crystalline powder that is water soluble and developed from an alkaloidal paste of the plant’s leaves. “Free base” and “crack” (“rock”) are popular cocaine products used for smoking. Free-base cocaine is vaporized in a water piper (bong) or even a soda can with a hole in it. “Crack” is the street name for cocaine bicarbonate pellets that are pea-sized and produced using ammonia or sodium bicarbonate (baking soda); heating this concoction to remove its hydrochloride component produces a “crackling” sound. Crack may be crushed, tobacco added, and then this “cigarette” is smoked; other chemicals often added include mannitol, quinine, or marijuana. Over half of the cocaine used on the streets is now crack cocaine because cocaine powder is decomposed when ignited to smoke. Crack cocaine has become relatively inexpensive and very popular with adolescents.

The 2013 YRBS noted that 5.5% of students had used any form of cocaine one or more times during their life [2]. The CDC surveys noted that the prevalence of ever used cocaine increased from 1991 to 1999 (5.9% to 9.5%) and decreased from 1999 to 2013 (9.5% to 5.5%) [2]. The prevalence of ever-used cocaine was higher among male youth versus female youth. Approximately 23% of Americans report they have experience with cocaine before age

30. The DSM-5 lists a number of stimulant-related disorders with regard to cocaine: stimulant use disorder-cocaine (mild, moderate, severe), stimulant intoxication-cocaine, stimulant withdrawal—cocaine, other stimulant-induced disorders-cocaine, and unspecified stimulant related disorder-cocaine [23].

Cocaine is a topical anesthetic, a peripheral sympathomimetic, and a central nervous system stimulant. The drug interferes with neuronal catecholamine reuptake and dopamine reabsorption. The popularity of cocaine is based on its ready availability and the potent euphoric feeling it produces; this high lasts 5 to 10 minutes if cocaine is smoked, in contrast to 10 to 30 minutes if taken intravenously. Because the high is short lived, the usual pattern of use is escalated and dependence is promoted. Urine and blood testing remains positive for 48-72 hours following its use. Once the euphoria is gone, irritability and fatigue set in. Users of this powerful drug develop severe psychological and physiological addiction along with tolerance. Serious physiological complications are infrequent and the death rate is low even in heavy long-term users; but, when they occur, they can be disastrous. A partial list of the serious side effects of cocaine is listed in Table 13.

Table 13. Adverse effects of cocaine

- | |
|--|
| – Anxiety |
| – Irritability and restlessness |
| – Confusion |
| – Peripheral blood vessel constriction |
| – Pupillary dilation |
| – Hyperpyrexia, tachycardia, and hypertension |

| – Nasal septum infection and perforation |
| – Frontal lobe infarction |
| – Intravenous needle complications (including hepatitis B, HIV/AIDS, endocarditis) |
| – Increased premature delivery |
| – Abruptio (bleeding between placenta and uterine wall) |
| – Adverse neurodevelopmental sequelae in infants |
| – Vascular spasm-induced limb reduction anomalies and strokes |

As with other drugs, addicts look to mix various drugs together to intensify the pleasant or euphoric feeling of their drug of choice. When alcohol is mixed with cocaine, cocaethylene is produced in the liver; this chemical heightens the cocaine euphoria (i.e., more potent and lasts longer), blunts some of the stimulant adverse cocaine effects, and increases the risk of sudden cardiac death 25 fold. The term, speedballing, refers to the mixture of cocaine and heroin (or morphine) and this combination also increases the risk for sudden death.

The method of using cocaine leads to various complications, as nasal perforation/infection with snorting and the infectious sequelae from intravenous use. The high abuse rate of cocaine is associated with increased risk of sexually transmitted diseases among adolescents and young adults; this includes HIV/AIDS, lymphogranuloma venereum, and

chancroid. Smoking crack may lead to the development of a very aggressive paranoia. Sudden death occurs and is a constant risk, whether it is the first time or the user is very experienced with this drug; such death is probably due to a terminal ventricular arrhythmia. Use of cocaine during pregnancy can lead to a variety of adverse effects on the fetus including preterm-labor, placenta infarction, placental abruption, pre-eclampsia, impaired fetal growth, and neurodevelopmental defects [54].

Management of Cocaine Addiction

While acute intoxication is usually not severe, it may be complicated by the use of opioids, alcohol, marijuana, and other drugs. Emergency management includes the maintenance of an airway and naloxone if opiate use is suspected. Treatment of arrhythmias may require lidocaine, phenytoin, or cardioversion. Lorazepam or diazepam can be used for severe agitation or seizures. Nitroprusside or labetalol can be used for hypertension. A cooling blanket and intravenous fluids may be used for hyperthermia. Phenothiazines are contraindicated.

Cocaine addiction is a difficult central nervous system disorder to manage. If tachycardia and hypertension develop while on cocaine, short acting beta-blockers and short-acting direct vasodilators (as esmolol) may be helpful; clinicians should avoid long-acting vasodilators, since cocaine intoxication is typically a short, self-limited phenomenon and use of these other drugs (as morphine, propranolol, thorazine) may lead to severe hypotension. Though naloxone is helpful for opioid addiction, it does not help with cocaine addiction.

Cocaine addicts with ADHD may observe that methylphenidate calms them down along with improving their concentration abilities; a reduction in cocaine use has been observed in some cocaine addicts who have ADHD and use methylphenidate.

Current addiction research seeks to find a way to stop the potent euphoric effects of cocaine and enable the motivated abuser to stop this drug. Dependence on cocaine involves various pathways (i.e., noradrenergic and dopaminergic) in the primitive midbrain reward center. Multiple CNS sites are involved with the addiction and thus any drug used to help the addict must work over many CNS areas. Table 14 lists proposed drug mechanisms that are being researched to potentially manage cocaine addiction by blocking this drug’s many effects, including the use of vaccine technology [55].

Table 14. Potential mechanism to manage cocaine addiction

– Bind to cocaine molecules and prevent movement into the CNS via the blood-brain barrier – Change cocaine molecules into harmless (inactive) particles – Remove the cocaine molecule as a vaccine using an antibody-type response – “Catalytic” antibodies changing cocaine into inactive fragments
--

For example, research is looking at drugs called “peripheral blockers,” such as Dopamine D3 Receptor Agonists (D3 agonists), to prevent cocaine-induced CNS stimulation by neutralizing this drug in the blood; such drugs may help with addiction as well as with overdose and cocaine-induced seizures. Oxytocin may be helpful via effects on the glutamate

receptor systems [56]. N-acetylcysteine is also under active research for the management of cocaine dependence.

If the addict uses other drugs, treatment of dependence on those other drugs may help. For example, naltrexone or disulfiram may help with alcohol abuse and be of benefit to the addict who uses both cocaine and alcohol.

OPIOIDS

A number of opiate narcotics are abused by adolescents and adults, as reviewed in Table 15. The DSM-5 lists a number of opioid-related disorders: opioid use disorder (mild, moderate, severe), opioid intoxication, opioid withdrawal, other opioid-induced disorders, and unspecified opioid-related disorders [23].

Prescribed narcotics have been popular for many years, and are available in many ways, as stealing them from home medicine supplies, obtained from emergency room or office clinicians by faking (exaggerating) injuries or illnesses (i.e., migraine headaches, dysmenorrhea), or simply buying the opiate of choice on the street. Most are obtained free from friends or bought from school mates. The 2008 MTF reports use by 10% of 12th graders with Vicodin being the choice of 9.7% [49]. Oxycontin use was reported by 2.1 and 4.7% of 8th and 12th graders respectively. Seven of the top 11 abused prescription medications are opiates.

Table 15. Narcotic opiates

- | |
|---|
| <ul style="list-style-type: none">– Codeine– Fentanyl– Heroin– Meperidine– Methadone– Morphine– Oxycodone– Pentazocine– Propoxyphene– Others |
|---|

Clinicians may forget or not be aware of the addictive potential of such classic analgesics as Darvocet®, Dilaudid®, Percocet®, Stadol®, Vicodin®, or Ultram®. News media have covered the recent increased popularity of Oxycodone (OxyContin®), a narcotic that is abused by some in place of heroin; a variety of ways of abuse are noted, including chewing an oxycodone tablet, crushing the pill and either snorting the contents or intravenous use after boiling the powder. Its acceptance by addicts is reflected in the many street names it has acquired, including OXY, OC, oxycotto, and killers. Fentanyl is a prescribed narcotic that is ten times more potent than heroin and there are a number of reported overdoses from this drug.

HEROIN

Inexpensive and potent heroin (diacetyl morphine hydrochloride) is available and comes from Mexico, Columbia, Afghanistan, and Pakistan. Heroin (junk, smack, Mexican brown, China white) can be abused in a snuff form, intravenously, or subcutaneously (skin-popping). China White is 2000 times more potent than morphine and responsible for some 28 documented fatalities. Speedballing, as noted above, refers to the combination of heroin or morphine with cocaine in an effort to block the sedative effect of heroin. Use of both heroin and morphine is called “New Jack swing.” “Cheese” which blends black tar heroin and Tylenol PM® has been associated with 12 deaths in the United States.

The mean age of heroin use dropped from 27 years of age in 1988 to 19 years of age in 1995. There was a doubling of high school seniors who used this drug from 1990 to 1996 at a time when the price of heroin was dropping along with a 40% increase in drug purity. The purity of available heroin has increased from 5% in the 1990s to over 80% presently. The 1999 YRBS noted that 2.4% of high school students had tried heroin on at least one occasion; this was broken down to 3.5% males and 1.3% females. The 2003 Monitor the Future (MTF) Study recorded that 1.5% of high school seniors had a lifetime use of heroin, 0.8% over the past year and 0.4% over the past survey month [49]. The lifetime heroin use for these seniors was 1.5% in the 2007 YRBS, and < 1% in the 2008 MTF Study. The 2013 YRBS reported that 2.2% of students had used heroin one or more times during their life and this decreased from 2.9% in 2011 to 2.2% in 2013 [2].

Unfortunately, this use increases as these seniors leave school and also increases in those who drop out of school before graduation of their peers who stay in school. The typical situation is an adolescent who begins to snort this drug, then develops an intense craving for the resultant euphoria, and progresses to smoking or intravenous use (mainlining). An all-consuming addiction with tolerance develops, as noted by the saying: “once is too much, 1000 times not enough;” also classic, is the development of physical addiction, psychological dependence, and a narcotic withdrawal syndrome. This may follow initiation of abuse by as little as several weeks. Approximately 30% of adolescents who smoke heroin become mainlining adults. Those who smoke or snort this drug often mistakenly feel they are bypassing the dangerous effects of heroin by smoking. However, this is not true, and the younger the addiction starts, the greater is the risk for post-cessation relapse.

Opiate overdose presents with the triad of respiratory and CNS depression associated with miotic constriction of the pupils. Mydriasis is seen with withdrawal which presents with flu-like symptoms, lacrimation, irritability, abdominal cramps and diarrhea. Cardiopulmonary failure with bradycardia, hypotension, and pulmonary edema can occur. A rapid response to the opiate antagonist naloxone is diagnostic of opiate overdose. Support of both respiratory and circulatory systems with airway maintenance is imperative. Correction of hypotension is necessary while monitoring for hypoglycemia, pulmonary edema, and arrhythmias. Thin-layer chromatography immunoassay will detect opiate metabolites for 2-3 days.

Table 16 lists some of the medical complications of heroin abuse, including an overdose that leads to death from respiratory depression and pulmonary edema. For example, an increase in heroin overdose deaths in 28 states was reported by the CDC for the period 2010 to 2012 [57]. Clinicians should observe for the use of tattoos to obscure puncture wounds or needle-tract marks made by the heroin intravenous abuse; such mainlining and tattooing

phenomena increase the infectious complications of needle use. A newborn withdrawal syndrome is described in newborns whose mothers abuse narcotics; heroin withdrawal in utero can lead to meconium aspiration, bile pneumonitis, and severe respiratory distress.

Table 16. Medical complications of heroin abuse

Management of Opioid Addiction

Addiction research of the last part of the 20th century led to the conclusion that opioid dependence is a neurobiological central nervous system disorder that involves brain receptors. This science looks at reward circuits controlling such processes as hunger, thirst, reproduction, and even drug addiction. Drug-induced alterations in CNS opiate receptors lead to drug dependence and tolerance phenomena. Opiate addiction induces significant social dysfunction with complex biological and psychological components that are not corrected by incarceration. Unfortunately, the majority of such addicts are not in treatment designed to manage their brain disorder. These patients often need acute detoxification measures followed by residential and/or outpatient management of sufficient nature to blunt their often overwhelming need to find the narcotic euphoria. Community programs as the 12-Step groups (i.e., Narcotics Anonymous) can be very helpful to these individuals to stay off the drug(s).

The opioid addict may benefit from the judicious use of various medications that are available as part of the overall management program (see Table 17) [7]. Naltrexone (ReVia[®], Depade[®]) is an opiate antagonist that can help many with opiate addiction, including addicts with additional alcohol dependence. Methadone may block classic narcotic effects without giving the user the classic opiate euphoria; it can also remove withdrawal symptomatology and help with on-going desires for additional drugs. Clinicians have used this drug as a substitute agonist for opiate dependence since the 1960s. Pharmacokinetics allow once a day dosing and the patient officially must be at least 18 years of age or older. Daily doses may range from 40 mg to 400 mg and successful patients, while on methadone, are then able to maintain a more normal life, in contrast to the addict's chaotic life of only seeking money for another high.

In search of longer-acting alternatives to methadone, addiction specialists have turned to levomethadyl acetate and buprenorphine, both of which are medications that are effective with narcotic addicts. Clinicians can also use the sublingual combination of buprenorphine/naloxone (Suboxone®) that provides benefit at least equal to that of methadone and seems more efficacious than detoxification/counseling. The naloxone part of this dual treatment is used to stop diversion of the buprenorphine to intravenous administration. There have been some reports of ventricular tachycardia with prolonged QT intervals (Torsade de pointes) after taking LAAM and more research is needed to see if this drug is safe enough to be used.

Table 17. Medications available for opioid addiction

–	Naltrexone
–	Methadone hydrochloride
–	LAAM (levo-alpha-acetyl methadol or levomethadyl acetate)
–	Buprenorphine
–	Anti-depressant drugs (as selective serotonin reuptake inhibitors)
–	Anti-stress medications (as buspirone)

HALLUCINOGENIC DRUGS

Both the hallucinogens and dissociative drugs may alter a youth’s state of mind and mood. Hallucinogens include Psilocybin, Psilocyn (Shrooms, mushrooms), LSD, and mescaline (peyote); these drugs can cause auditory, visual, and tactile hallucinations. Dissociative drugs, such as Ketamine or PCP, alter a persons’ state of mind and mood, causing a “feeling of detachment” or “dissociate reaction,” but do not cause hallucinations. The 2013 YRBS noted that 7.1% of surveyed students report having used a hallucinogenic drug one or more times during their lifetime [2]. From 2001 to 2013 the prevalence dropped from 13.3% in 2001 to 7.1% in 2013.

The DSM-5 lists a number of hallucinogen-related disorders: phencyclidine use disorder (mild, moderate, severe), other hallucinogen use disorder (mild, moderate, severe), phencyclidine intoxication, other hallucinogen intoxication, hallucinogen persisting perception disorder, other phencyclidine-induced disorders, other hallucinogen-induced disorders, unspecified phencyclidine-related disorder, and unspecified hallucinogen-related disorder [23].

PCP (phencyclidine) and LSD (lysergic acid diethylamide) are taken as pills to induce a potent reality distortion with synesthesias or alterations of sensory perception (involving sight and sound) and emotions (involving euphoria and intense fears), in addition to time and place. Tolerance is described in these individuals as are cases of psychosis and the well-known flashback that can be induced by antihistamines or marijuana. Overdosing can induce respiratory depression with coma and death. A recent addition to the “trip” scene is *Salvia divinorum* (Virgin Mary’s Herb, Mary’s leaf). This is a hallucinogenic ethnobiological plant grown in the southwest U.S. which may be smoked, squeezed into water, or steeped into a tea. It is absorbed through the mucus membranes and produces a “euphoric experience with God.” It cannot be detected by current urinary drug screens.

PHENCYCLIDINE (PCP)

This drug has many street names, including peace, pill, sternly, peace pill, angel dust, hog, and sheets. PCP is an arylcyclohexylamine that can be made in illicit laboratories; it causes adrenergic potentiation by inhibition of neuronal catecholamines. PCP can be taken as tablets, liquid, or in a powder form, sometimes sprinkled on marijuana or cigarettes (joints) to augment pot's potency. It is a dissociative anesthetic with hallucinogenic, stimulant, and depressive properties. Since it is lipophilic it has a 72 hour half-life. PCP is the active ingredient and can be detected for up to eight days after ingestion. Clinical expression may include frank psychosis, mania, delirium, and late manifestations of depression. Agitation associated with vertical and horizontal nystagmus, miotic but reactive pupils, elevated blood pressure, gait ataxia, and delusions should suggest PCP intoxication.

Diagnosis can be confirmed with gas chromatography/mass spectrometry using blood levels with or without urine testing. Excretion is pH dependent (increased in acid pH) High doses of dextromethorphan, especially when mixed with benzodiazepines, have been associated with a similar toxicity to phencyclidine.

Management of a PCP-induced "trip" (bad reaction) involves keeping the patient in a dark, padded room with the provision of diazepam (10-20 mg orally, or 10 mg intramuscularly every four hours). Lorazepam (1-2 mg) may be used IM/IV for seizures. Haloperidol may be reserved for severe agitation. Death may be caused by PCP because of the development of hypothermia, seizures, trauma, severe hypertension or hypotension, and/or psychotic delirium/coma. However, most deaths are caused by accidental injury occurring during intoxication. Psychosis may be helped with D3 agonists and research seeks chemicals to act as "antibodies" to neutralize PCP molecules.

LYSERGIC ACID DIETHYLAMINE (LSD)

LSD is the most powerful hallucinogen and has earned many street names, including acid, "L," sugar, dots, cubes, big "D," and blotters. LSD is found in morning glory seeds and rye fungus (Ergot). It is easy to produce by amateur chemists and easy to hide since it is odorless, tasteless, and colorless; because of this, it has become popular at marathon dances ("raves") where it can be given to unsuspecting victims. A dose as low as 20 mcg (placed on small objects as a sugar cube, paper blotter, or postage stamps) can lead to its classic euphoric or hallucinogen effects by increasing serotonin; sympathetic activity is potentiated with resultant tachycardia, fever, conjunctival injection, mydriasis, lacrimation, flushing, dry mouth, blurred vision, tremors, incoordination, and elevated blood pressure. Onset of symptoms following an oral dose is 30-45 minutes. The half-life is 3 hours, but routine urine drug screens do not detect LSD. Most youth with a bad trip or unpleasant flashback respond to a reassurance and calm interaction with the clinician; if necessary, haloperidol has been given for major reactions, including prolonged seizure activity.

TRYPTAMINES

Tryptamines include a number of naturally occurring Schedule I hallucinogenic substances obtained from “magic mushrooms” indigenous to South America, Mexico, and the United States. They can be synthetically produced and include Psilocybin (0-phosphoryl-4-hydroxy-N, N-dimethyltryptamine) and Psilocyn (4-hydroxy-n, n-dimethyltryptamine). These chemicals produce muscle relaxation, mydriasis, vivid auditory and visual distortions, as well as emotional lability. These drug effects are not well predictable and vary by the specific mushrooms used as well as the manner in which they are dried, brewed, and consumed. Users of tryptamines often experience a multitude of effects that include hallucinations, euphoria, dilated pupils, empathy, emotional distress, “feelings of love,” and visual-auditory disturbances or distortions. Some experience gastrointestinal effects, as nausea, emesis, and diarrhea.

Dimethyltryptamine (DMT) occurs naturally in a variety of wild plants and seeds. It is usually smoked, sniffed, or injected. DMT is inactivated orally and rapidly metabolized. The drug experience is called a “businessman’s trip” because its effects are for only one hour. Diethyltryptamine (DET) is an analogue of DMT and produces the same pharmacologic effects, but is less potent than DMT. Alpha-ethyltryptamine (AET) is another tryptamine class hallucinogen added to the list of Schedule I hallucinogens in 1994.

N,N-Diisopropyl-5-methoxytryptamine (referred as “Foxy-Methoxy”) is an orally active tryptamine recently encountered in the United States. Alpha-methyltryptamine (AMT), known as “spirals,” was designated a Schedule I drug in 2003. Tryptamines, like “Foxy” and AMT, are very dose dependent, which means that the doubling of a moderate dose could result in effects similar to LSD. The duration of effects from 20 mg of AMT usually last between 12 and 24 hours, while the effects from 6 to 10 mg of Foxy reportedly last from 3 to 6 hours. 5-methoxy-alpha-methyltryptamine (5-MeO-AMT) is also a tryptamine. Other common names for 5-MeO-AMT are “alpha-O,” “alpha” and “O-DMS.”

Bufotenine (bufagin, bufotenin, 5-hydroxy-N-N-dimethyltryptamine) is a Schedule I substance found in certain mushrooms, seeds, and most notably, the skin glands of the green and red Cane Toad (*Bufo marinus*). In the 1960s-70s, the “toads milks” in northern Florida were obtained by daring to lick (“suck the toad”) which lead to accidental handling of the toads. Historically, these toads were killed and their skin boiled to produce a bitter tasting broth. In Australia, the milk is dried into a powder and smoked. In South America, this substance is used as snuff. A mild, though frightening “trip” occurs as this 3-indoleamine works on serotonergic sites in the amygdale and ventral lateral geniculate. The toad can continuously replace the supply and, in general, most bufotenine preparations from natural sources can be extremely toxic.

MDMA (ECSTASY)

Phenethylamines are a family of over 100 chemicals that are hallucinogenic. MDMA (3,4 methylene dioxymethamphetamine) is a phenethylamine that resembles both a stimulant (methamphetamine) and a hallucinogen (mescaline). The U.S. Food and Drug Administration classified MDMA as a Schedule I drug in 1985. MDEA (3,4-methylenedioxy-N-ethyl-

amphetamine) or Eve is a close congener of MDMA. There is also a designer version of the banned decongestant and “diet” drug, phenylpropanolamine; it is referred to as U4ia and is similar in action to MDMA with both stimulant and hallucinogenic effects.

MDMA was developed in 1912 by German scientists and synthesized as an appetite suppressant; it was utilized in the 1970s and 1980s in an attempt to improve psychotherapy. Concern over this drug developed as its severe side effects became evident.

The 2013 YRBS reported that 6.6% of students had used ecstasy (MDMA) one or more times during their lifetime and this dropped from 11.1% in 2001 to 6.6% in 2013 [2].

MDMA produces an intense euphoria and energizing effect in users and thus is popular at dance or club halls (called “raves, trances, or dance parties that last all night”); it is also popular with college students. It is a designer drug that abusers feel is safe at 1-2 mg/kg and produces prolonged effects; because of this, its availability and use is more common than cocaine at teenage raves. Its effect is normally 3 to 6 hours, though it may be several days. Its purest form is as a white crystalline powder and if red or brown MDMA is found, this suggests impurities are present. MDMA has many street names, such as ecstasy, XTC, X, hug drug, lover’s speed, diamonds, clarity, dex, essence, roll, bean, M, E, and Adam.

MDMA has mescaline like effects, probably due to interaction with and destruction of serotonergic neurons in the central nervous system that are involved with thought and memory. This may result from the formation of quinones which can combine with glutathione and other thiols. MDMA produces an anxious state of “well-being,” changes in perception, moderate derealization and depersonalization without producing psychomotor agitation. MDMA abuse may lead to cognitive dysfunction, memory impairment, and behavioral problems. If taken during pregnancy, the risk for congenital anomalies is increased. Users take MDMA to enhance sensual awareness and augmented psychic or emotional energy. A number of side effects are noted, as listed in Table 18.

Table 18. Side effects of MDMA

- | |
|---|
| <ul style="list-style-type: none">– Hypertension and increased pulse– Dehydration and possible heat stroke– Fatigue– Sleep dysfunction– Muscle spasms– Sweating– Organ dysfunction: renal, liver, CNS, muscular– Intracerebral hemorrhage– Irreversible CNS damage with memory loss in chronic abuse– Confusion and paranoia– Psychosis– Depression– Anxiety, including panic attacks |
|---|

MDMA can hide thirst and eventual death that may be due to dehydration (which is not uncommon and hence its association with water bottles at raves), hyperthermia, hyponatremia, or cerebral edema. High doses can lead to muscle breakdown, breakdown of muscles, malignant hyperthermia, renal failure, and cardiovascular failure at the raves. MDMA and some of the other “designer” drugs have been associated with intracerebral

hemorrhage in adolescents and young adults who have undiagnosed vascular malformations. Also, anxiety (including paranoia and panic attacks) may last for weeks after drug cessation. MDMA is a popular date-rape drug (see below). Acute management requires diagnosis, rehydration, cardiovascular support, and the use of benzo-diazapines for sympathomimetic effects.

MDMA users may mix this drug with alcohol, marijuana, LSD, dextromethorphan, and other drugs. Preparations with camphor, menthol, and ephedrine are applied to the nasal mucosa or chest to enhance the desired MDMA effects. MDMA can also be taken in increasing doses in a “stacked” schedule similar to that used with anabolic steroids. The drug user may also take chemicals that are ecstasy-like in appearance, such as ketamine (“special K”), alpha-methyl fentanyl (“synthetic heroin,” “china white”) and ephedrine tablets (“herbal ecstasy,” “Chinese ephedra,” “Ma Huang”); large amounts of these chemicals may lead to hypertension, cardiac arrhythmias, myocardial infarction, cerebrovascular accidents, and death. The ephedrine found in Herbal ecstasy products as found in “health” food stores has only recently been banned.

“DATE RAPE” DRUGS

Novel and more creative uses for previously legitimate pharmaceuticals and “nutriceuticals” continue to emerge “on the street,” including familiar drugs as marijuana (i.e., increased THC content), phencyclidine (PCP), crack cocaine (or opium) with Viagra, variations on MDMA described previously, short acting benzodiazepines (“benzos”), and those compounds readily made using recipes available on the internet and concocted by amateur chemists.

|--|

A variety of chemicals have been used to lower external and internal inhibitions and/or consciousness, helping to facilitate sexual assault. These so-called “date rape” drugs are named for their strong sedative and hypnotic effects that are enhanced with alcohol. They continue to be popular at all night dance parties or “raves,” and thus, have also been called Club Drugs or Party Drugs. Some are sold in “nutrition” stores or via magazine ads as sleep aids, muscle builders, and even as “party drugs.” A variety of drugs have been used, as

partially listed in Table 19; this list includes MDMA-methylenedioxy-meth-amphetamine (Ecstasy) previously discussed.

FLUNITRAZEPAM (ROHYPNOL®)

This is a potent benzodiazepine with sedative, anxiolytic, and anticonvulsant effects. It belongs to the same group as Halcion, Ambien, Xanax (Z Bars), Klonopin, Sonata, Versed, and Valium. Flunitrazepam is a central nervous system depressant produced commercially in Switzerland that reduces inhibition and results in memory loss (blackouts) with short term anterograde amnesia for activity that takes place while under the influence of the drug.

It can also lead to such adverse effects as urinary retention, drowsiness, confusion, dizziness, gastrointestinal dysfunction, visual disturbances, hypotension and others. It is available by prescription in Europe (not the United States) and used as a sedative for management of insomnia and also as a pre-surgery anesthetic.

Flunitrazepam is a tasteless, odorless, and colorless chemical that can be taken as a pill or dissolved in a beverage; anecdotal reports of snorting are noted as well. One milligram can be secretly placed in a liquid to sedate a victim for 8 to 12 hours with unfortunate amnesia for the sexual assault that may follow the ingestion. The victim is seen voluntarily leaving with the rapist, recalls little if anything of the events, and is unable to testify in any later prosecution. It has become a popular and classic date rape drug used by gang members and even high school or college students operating at local parties. Its many street names include forget-me pills, Rope, Roche, Mexican valium, and roofies. It is also an addictive drug used voluntarily by youth as an alternative or adjunctive drug to marijuana or LSD, as well as the self-treatment of anxiety. Its effects are enhanced with alcohol. If used on a regular basis, increasingly higher doses are needed for the desired euphoric effect. Its use has increased 50% over the past several years. In South Texas, along the United-States-Mexico border, it is frequently replaced by the more readily available Klonopin or Xanax, both of which are associated with blacking-out spells and “withdrawal seizures,” especially when abused with alcohol and marijuana.

GAMMA-HYDROXYBUTYRATE (GHB)

This is a CNS depressant that induces euphoria and lowered inhibition. It has many street names, including: Liquid X, Liquid E, Liquid XTC, Liquid Ecstasy, Natural Sleep-500, Organic Quaalude, G Caps, Gamma Hydrate, Georgia Home Boy, Growth Hormone Booster, Cherry Meth, Sodium oxybutyrate, Somatomax PM, Grievous Bodily Harm, G-Riffick, Oxy-Sleep, Scoop, Fantasy, Easy Lay, Soap, Salty Water, Vita G, Gamma OH, Somsanit, GHB; Liquid Ecstasy; G; Georgia home boy, caps, organic qualude, and goop.

Like Rohypnol, GHB and its analogs are used as “date rape” drugs. It has a soapy or salty taste, and hence the name salt is used until it is mixed with any liquid, including water. Because it is colorless, tasteless, and odorless, it is easily and quietly slipped into an unattended party drink to induce sedation and amnesia. Effects develop in 10-20 minutes, peak in 1 to 2 hours, and last for 4 hours. GHB is rapidly cleared from the body and is

undetected in subsequent rape investigations. The clinician providing care in an emergency situation must request that the laboratory specifically look for GHB. Adolescent females need to be warned about the danger of leaving drinks unattended.

It is used by bodybuilders and athletes because of beliefs that GHB will augment endogenous human growth hormone (HGH) release while sleeping. GHB is available in single doses that augment or mimic effects of alcohol; increasingly higher doses are needed for desired effects. The risk of seizures and death caused by GHB-induced respiratory depression is raised when mixing GHB with other drugs, such as alcohol, heroin, LSD, and psilocybin. The CNS depression occurs because of increasing CNS dopamine and GABA (gamma-amino-butyric acid); the endogenous opioid system is also activated. It became a Schedule I substance in March of 2000 and in July, 2002, GHB was approved by an FDA advisory committee for study in the treatment of cataplexy. Most of the GHB used in the United States is illegally manufactured in the US. Law enforcement in every region of the United States reports that GHB has surpassed Rohypnol as the most common substance used in drug-facilitated sexual assaults.

GAMMA-BUTYRO-LACTONE (GBL)

Because the DEA is cracking down on GHB use, some are using GHB precursors, such as GBL as well as BD (1-4 butanediol), an industrial solvent; both are promoted to enhance sexual ability and pleasure. Street names for GHL are many, including Renewtrient, Revivarent, Reivivarent G, Blue Nitro, Blue Nitro Vitality, GH Revitalizer, Gamma G, Remforce, and Soap; it is found in paint thinners and floor stripper products. BD leads to bradypnea and can induce emesis, aspiration, and coma. GBL and BD are both easily changed to GHB in vivo, and in vitro by adding water. Some producers are substituting BD for GHB, even though the FDA has identified BD as a potentially life-threatening drug. It is sold as a dietary supplement in a number of sleep aid and muscle enhancing products; names include SomatoPro, NR63, Thunder Nectar, Enliven, GHRE, Weight Belt Cleaner, Revitalize Plus, and Serenity. The FDA asked that products with GBL be recalled in January, 1999; some states, such as California, have told manufactures that it is illegal to sell these products or market them as a supplement or nutritional substance. GBL-related products have been associated with reports of at least 55 adverse health effects, including one death. In 19 of these cases, the consumers became unconscious or comatose, several requiring intubation for assisted breathing.

KETAMINE

This drug has been approved since 1970 in the role of an injectable airway-preserving veterinary anesthetic; it is taken orally to induce dissociative states, described as dream-like and hallucinatory. Street names include K, Cat Valium, Special K, and Vitamin K. It can be obtained as a white powder that can be added to tobacco or marijuana or the powder can be snorted; intramuscular abuse is also described. The effects of ketamine last one half to two hours producing an “out of body” distortion of time and space. Ketamine in low doses can

lead to dysfunction of learning ability, memory, and attention span; in high doses, it can lead to myalgia, paranoia, elevated blood pressure, delirium, motor function impairment, amnesia, long term flashbacks, and respiratory depression-induced death. There is no urine metabolite.

INHALANTS

Inhalant drugs (see Table 20) are central nervous system depressants typically abused by young (ages 6-8, peaks at 14), often male, and homeless adolescents to induce temporary euphoria and excitement [58, 59]. These inhaled chemical vapors are viewed as easily available and as inexpensive substitutes or precursors to other drugs, such as alcohol or marijuana. Delivery is by “sniffing, huffing, or bagging.”

In 1995 the lifetime use was 21.6% for 8th graders versus 19.7% in 1999 and 17.3% in 2004 [60]. Approximately 5% of adolescent girls (age 12-17) used inhalants that included nitrous oxide vials (19.3%), glue sniffing (34.9%), correction fluid (23.4%), hair spray (23%), and inhalation of paints or sprays (6-16%) [49]. The 2013 YRBS reported that 8.9% of students had sniffed glue, breathed the contents of aerosol spray cans, or inhaled any paints or sprays to get high one or more times during their life [2]. The prevalence dropped from 20.3% in 1995 to 8.9% in 2013.

The main ingredient in airplane glue and some rubber cements is toluene. Another popular inhalant is gasoline, noted especially in rural areas of the United States and with Native American adolescents. Amyl nitrite, butyl nitrite, and other volatile nitrates are found in room deodorizers and are used by older adolescents to induce “aphrodisiac” effects.

Table 20. Types of inhalant drugs*

Solvents	Gases	Nitrites (Aliphatic nitrites)
Industrial or household solvents or solvent-containing products	Gases used in household or commercial products	Cyclohexyl nitrite (available to general public)
Paint thinners or solvents	Butane lighters	Amyl nitrite (available only with prescription)
Degreasers (dry-cleaning fluids)	Propane tanks	Butyl nitrite (Illegal substance)
Gasoline	Whipping cream aerosols or dispensers (whippets)	
Glues	Refrigerant gases	
Art or office supply solvents	Household aerosol propellant and associated solvents	
Correction fluids	Found in spray paints	
Felt-tip-maker fluid	Found in hair or deodorant sprays	
Electronic contact cleaners	Found in fabric protector sprays	
	Medical anesthetic gases	
	Ether	
	Chloroform	
	Halothane	
	Nitrous oxide

Table 21. Effects of inhalants*

Hearing loss
Toluene (paint sprays, glues, dewaxers)
Trichloroethylene (cleaning fluids, correction fluids)
Peripheral neuropathies or Limb spasms
Hexane (glues, gasoline)
Nitrous oxide (whipping cream, gas cylinders)
CNS or Brain Damage: toluene
Bone Marrow Damage: benzene (gasoline)
Liver and Kidney Damage
Toluene-containing substances
Chlorinated hydrocarbons
Correction fluids
Dry-cleaning fluids
Blood Oxygen Depletion/ Methemoglobinemia
Organic nitrites (“poppers,” “amyl,” “bold” and “rush”)
Methylene chloride
Varnish removers
Paint thinners
Loss of the sense of smell (nitrites)
Thermal burn injury with nebulized alcohol/Robitussin® (“RoboFires”)
Death
Kaposi’s sarcoma

*adapted from Greydanus DE, Patel DR: Substance abuse in adolescents: A complex conundrum for the clinician. *Pediatric Clin North Amer* 59(5): 1179-1223, 2003. (with permission).

Inhalant use is usually experimental and may occur as a group activity. Inhalation occurs after these substances are placed in a plastic bag (“bagging”), wrap, or inhaled from a soaked rag (“huffing”) to induce the intoxicating (psychoactive) effects. Absorption is rapid and the altered mental state lasts for 5-15 minutes. After a mild stimulatory effect, an inhibition reduction occurs, followed by unconsciousness. Death may occur from cardiac arrhythmias. Tolerance develops after long term use, though withdrawal is rare; dependence may develop [61].
